

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XLVII., DELIVERED FEB. 4, 1833.

GENTLEMEN,—It is scarcely necessary for me to say, that a dislocation cannot happen without a great deal of injury being done to the joint, and parts connected with it. Thus, it is evident, that the ligaments must be ruptured, which naturally keep the head of a bone from being thrown into the particular direction of the displacement; and, if those ligaments had been capable of adequate resistance, the bone could not have been moved out of its right situation. But, gentlemen, besides the capsular and other ligaments, the tendons and muscles may be torn. Thus, in the shoulder-joint, there is sometimes a rupture of the bicipital tendon; and when the head of the humerus is thrown into the axilla, the tendon of the subscapularis is torn. However, I wish you to remember, that the tendon of the biceps is not invariably broken; for, in Sir Astley Cooper's valuable work on Dislocations, you may find the particulars of the dissection of dislocated shoulders, proving that the bicipital tendon may neither be displaced from its groove, nor ruptured. In dislocations of the head of the thigh-bone, there will sometimes be a laceration of certain muscles, as of the adductor brevis and the pectinealis; and when the alteration in the length of the limb is considerable, several of the muscles will either be very much stretched, or preternaturally relaxed, in consequence of the distance between their origins and insertions being materially changed.

Let me now, gentlemen, offer a few general observations on the symptoms of dislocations. In the first place, I may remark, that an acci-

dent of this kind must produce a complete interruption of the functions of the joint. Then, the limb will either be shortened, lengthened, or distorted,—one of these changes invariably taking place. When the limb is elongated, this symptom is of itself enough to convince you that the case cannot be a fracture; and this view will be confirmed, when you find that no crepitus can be felt. Another circumstance particularly meriting your notice is, that, in a dislocation, the axis of the bone is no longer natural. Thus, when the shoulder is dislocated, the axis of the humerus will not tend towards the glenoid cavity of the scapula, but towards whatever point the head of the bone may occupy, while its lower end will incline outwards, backwards, or forwards accordingly. You will also observe, that in dislocations, the natural prominences of the bones in the neighbourhood of the joint will be rendered either more conspicuous, or be more hidden than usual. Thus, in a dislocation of the shoulder-joint, the acromion will become, or will seem, more prominent, in consequence of the cushion of the shoulder being flattened by the stretched state of the deltoid muscle, and by the removal of the head of the bone from its situation. On the other hand, when the dislocation is of the hip, the projection of the trochanter major will be diminished. In some dislocations you will be able to feel plainly the head of the bone in the unnatural situation which it occupies; and if you attempt to rotate the limb, you will distinctly perceive that part of the bone moving in a place away from the articular cavity. Another common symptom of a dislocation is a hollowness in the situation of the joint, the head of the bone does not fill the articular cavity, and there is a remarkable depression, where none ought to exist:—thus, when the head of the humerus is out of its place, you may always feel such depression under the acromion.

There is another symptom, gentlemen, which particularly claims your attention, which is, that the dislocated bone cannot be moved with the same facility as if it were fractured; and hence there is a considerable rigidity about the

limb, which continues to increase after the accident, partly, as it is stated, in consequence of the muscles completing their contraction, and, as I think, partly from another cause, which is this:—after the bone has been some time out of its place, inflammation having had time to come on, the parts are more tender and painful, and, consequently, the patient naturally offers greater resistance to the limb being moved.

Dislocations also produce more or less swelling of the soft parts, which comes on very rapidly, especially when it is a ginglymoid joint that is affected. You might perhaps expect that such swelling would be likely to be followed by abscesses; but it is a fact, well known to all surgeons of experience, that however great may be the swelling and inflammation, consequent to a simple dislocation, they rarely lead to suppuration. However, a few instances are on record, as exceptions to this observation: thus, Sir Astley Cooper, in his work on Dislocations, mentions two examples, in which, after the reduction of a dislocation of the hip-joint, suppuration came on in the joint, and the result was fatal. But such an occurrence is very unusual.

The *prognosis* in dislocations, gentlemen, is a subject deserving of your attention. I noticed, in the last lecture, the increase of danger, produced by the circumstance of a dislocation being compound or complicated. It is not, therefore, necessary for me to say any thing more at present on that particular topic.

Old luxations, after they have continued for a certain time, cannot possibly be reduced; for not only do the muscles become shortened, and permanently adapted to the alteration in the length and position of the limb but the head of the bone acquires preternatural connexions, and generally becomes immovably fixed in its new situation by strong ligamentous bands. Indeed, in certain instances, a completely new socket is formed for it, so that it would be impossible to reduce the bone without first breaking away more or less of the sides of the new orbicular cavity. In unreduced dislocations of orbicular joints, particularly, nature makes very great efforts to restore the functions of the limb, often forming almost another joint where the head of the bone happens to be placed, and, as I have said, actually constructing a new socket for the head of the bone. In some cases, we also find that, after a certain time, the head of the bone undergoes a change in its shape and size; a circumstance illustrated in some preparations shown to you, in the course of the last lecture. We observe, that the head of the humerus, when it has been long out of its place, is not only diminished, but changed in shape. New ligaments are formed, calculated to hold the bone in the best position which circumstances will admit of; that is to say, ligaments so arranged as to afford the greatest possible support to the bone in its new situation,—the utmost support cir-

cumstances will allow; and sometimes, in order the better to effect this object, the new ligaments are immensely strong and thick. Thus, when the head of the humerus has been long out of its place, the glenoid cavity of the scapula will be filled up by a bony deposit; a new articular cavity be produced on the concave surface of that bone; and new ligaments will also be formed to hold the bone in its new socket. It is by means of such changes that nature makes a kind of substitute for the original joint.

I have stated that the natural socket, when no longer occupied, would be filled up, and more or less effaced; here gentlemen you see an instance, in which the glenoid cavity of the scapula is in a great measure obliterated by bony matter, in consequence of the head of the humerus never having been returned into it. In an unreduced dislocation of the hip, a new socket may form near the anterior inferior spinous process of the ilium, of which you see an example in the pelvis which I now show you. It seems as if the pressure of the trochanter major against it and part of the circumference of the original acetabulum has had a share in occasioning a change in its shape. In the next preparation, you observe that the head of the femur has been lodged upon the dorsum of the ilium, and the acetabulum is filled up; here also the pressure of the trochanter has altered the margin of the articular cavity, which had long been abandoned. Another preparation before us exemplifies very well the change which takes place in the glenoid cavity of the scapula, after the head of the humerus has been long removed from it; in fact, it is quite filled up with bony matter. Here also is another specimen, in which nature has succeeded in making a kind of new joint on the side of the pelvis, higher up than the original one, after a dislocation which had not been reduced. It is what some surgeons would term a *false joint*.

With respect to the question, what is to be done for dislocations which have continued a long time unreduced? the answer is,—nothing. A few instances are indeed recorded, where dislocations of the shoulder were reduced after three months had elapsed from the period of the accident; a space of time beyond which dislocations scarcely ever admit of being rectified; and I would wish you to remember, gentlemen, if excessive violence be used to reduce dislocations of long standing, serious and even fatal mischief may be the consequence. Five cases were published a few years ago, by one of the surgeons to the hospital at Rouen, where either the axillary vessels were ruptured, or the axillary plexus of nerves so contused as to render the limb ever afterwards paralytic; or so much injury was done to the soft parts by the pressure and extension employed, that mortification of the limb ensued. These facts should be a lesson to us, and put us upon our guard against applying too much force in our attempts to

reduce dislocations of long standing. No doubt, in the instances I have alluded to, there must have been a want of skill in the management of the force employed, as well as rashness in its degree; for Desault met with great success in reducing old luxations, several of which had continued as long as three months; and Baron Dupuytren has been still more successful, for some time ago he had reduced five and twenty dislocations of the shoulder and hip, which had existed for periods varying from a fortnight to upwards of three months. In modern times, surgeons are both more cautious and more skilful in their manner of applying force for the reduction of dislocations. Thus Dupuytren does not have recourse at once to a great degree of force, but takes measures calculated to lessen the resistance which is to be expected. Thus he employs bleeding, and puts the patient into the warm bath, so as to weaken the muscular system, and at the time of making the attempt at reduction, he is very particular in trying to divert the mind of the patient from the accident by conversation. In this manner the muscles are taken, as it were, by surprise; and without such judicious management, the muscles would be prepared to make vast resistance to the force employed for the reduction. In England, the same principles have long been familiarly known, duly valued, and successfully applied to practice.

What are called *original or congenital* dislocations, arising from imperfect development of the acetabulum, of course do not admit of a cure; there is no proper acetabulum; the dislocation has existed from birth, and is to be regarded as the effect of malformation. The case does, indeed, admit of some palliative measures, consisting of means designed to support the upper portion of the bone, which is principally accomplished by passing a belt round the pelvis.

Dislocations produced by disease, in other terms, such as are called *spontaneous*, are incurable; for the articular parts of the bones, and the cartilages and ligaments of the joint, are generally under these circumstances too much changed and impaired to leave any chance of a restoration of the parts to their natural condition again.

Gentlemen, in the treatment of dislocations, considered generally, there are three principal indications to be attended to. The first one, I scarcely need say, is to replace the bone in its proper situation; in every recent dislocation this is the first object to be fulfilled, and is called the *reduction*. The second indication, or that which claims attention directly the bone has been reduced, is to take measures to prevent it from slipping out of its place again. With this view, you direct the patient to keep the joint perfectly motionless and quiet, or even employ mechanical means for the purpose. The fulfilment of this indication also gives the ligaments and other parts which

have been lacerated, the best opportunity of uniting. The third indication is to adopt such plans as are most likely to moderate the inflammation and swelling, necessarily arising from the accident.

The reduction of the bone, then, is the first indication, and in order to be able to judge of the proper principles which are to guide you in effecting such reduction, you should first consider what is the nature of the resistance you have to encounter in making the attempt to put the bone back into its right place. Gentlemen, the chief impediment to the reduction, in a recent dislocation, you will find almost always to be caused by the action of the muscles, and the resistance from this source will be found to increase, in proportion to the length of time which the bone remains unreduced. In other words, I may say that you will always be able to replace the bone with greater facility, when you make the attempt soon after the occurrence of the accident; but if you neglect the reduction for a few days, you will find that the resistance has become very considerable, such as you may have great difficulty in overcoming.

That it is the action of the muscles, which is the chief obstacle in the reduction, is proved, first, by the facility with which the bone may be replaced when the accident has happened to a limb affected with paralysis; secondly, by the same facility with which a reduction is effected, when the patient accidentally faints, or when he has been suddenly debilitated by bleeding, or by nausea and sickness coming on at the moment when the attempt at reduction is made. In short, any circumstance, producing great temporary weakness, or extreme prostration of the vital power, and thereby occasioning a sort of collapse, and incapacity of resistance in the muscular system, will always render the reduction of a dislocated bone more easy. Another proof, that the muscles are the agents, making the resistance, is afforded by the circumstance, that, if the mind of the patient be diverted from the accident, and directed to other objects at the time of making the attempt at reduction, the surgeon's design is much more easily effected. He then take the muscles by surprise, as it were; but if the attempt to force the bone into its place be made, while the patient is alarmed, and on the watch, then the muscles will act with their utmost power, and often frustrate every endeavour on the part of the practitioner to accomplish the reduction. These facts furnish useful hints in practice; they teach you, not only how to avail yourselves of any accidental swoon or temporary weakness of the system, but, in difficult cases, suggest to you, that you ought to bring on this weakness artificially; and, in fact, this is what the best modern surgeons frequently do; when they cannot effect the reduction, in consequence of the powerful resistance of the muscles, they bleed the patient largely from a considerable orifice in the vein,

or they administer tartarised antimony, so as to produce nausea, or they give opium, and, as it were, intoxicate the patient with it; for it is found, that, when a person in a state of inebriety meets with a dislocation, the reduction is more easily effected, while he is in this condition, than afterwards, when the influence of drink has subsided, and his muscular power has returned. Here, gentlemen, we have convincing proofs, that the chief difficulty in the reduction of ordinary dislocations arises from the resistance of the muscles, connected with the dislocated bone.

Of course, you would not bleed, or administer tartarised antimony, if you could accomplish the reduction easily without those means.

Then, gentlemen, it is hardly necessary to say, that the reduction of a dislocated bone requires the employment of mechanical force; some degree of which is manifestly indispensable to bring back the head of the bone into its proper situation. You will remember I told you, that, in some dislocations, two kinds of displacement happen; the one, *primary*, which occurs directly after the accident; the other, *secondary*, which takes place afterwards. The head of the bone is thrown into a particular situation in the first instance, and then may change its place again, in consequence of the action of the muscles. But, gentlemen, you are not to suppose there is this further change—this secondary displacement—in all dislocations: generally, it occurs only in those of ball and socket joints. In practice it will be useful for you to understand this fact, because you ought generally to make your first extension in such a way as to dislodge the bone from the particular situation, into which it has been carried in its secondary displacement. Hence, the first extension is usually made in the direction of the axis of the dislocated bone; and it is so made, in order that the head of the bone may follow, as nearly as possible, the same course on its return, as it took in quitting the place into which it was thrown in its first or primary displacement. In fact, the first extension is influenced, in respect to its direction, by the consideration of the effect of the secondary displacement.

In some cases, no sooner is the secondary displacement removed, than the action of the muscles alone is sufficient to draw the head of the bone back into its place.

Now, gentlemen, another fact is obvious, namely, if merely *extension* were employed, you would not succeed in reducing a dislocated bone; for you would pull the patient off his bed or chair, instead of effecting your object. It is, therefore, necessary to fix him in such a way, that he shall not yield to the extending power; and, with this view, what is termed *counter-extension* becomes necessary as well in dislocations, as in fractures, and even more so, because the extension, required for the reduction of a dislocation, is much greater than that necessary for the reduction of a

fracture. Thus, when you are reducing a dislocation of the thigh-bone, or the humerus, you are obliged to fix the pelvis, in the first case, and the thorax and scapula in the second, which is commonly done by means of a girth, or bandage of some kind or another. Extension would evidently be of no use, unless counter-extension were employed at the same time. In France, the counter-extension, in the treatment of a dislocated shoulder, is generally made by the assistant holding a sheet or long tablecloth round the chest; and the same plan is sometimes employed in this country; but, in many instances, other methods are employed by surgeons in England: the counter-extending means being fixed to a staple in the wall, to a post, or any other sufficiently firm point. On the continent, surgeons often prefer making the extension and counter-extension, as far as possible from the dislocated joint; for example, in a dislocation of the thigh-bone, they apply the extending power to the lower part of the leg; but, in England, it would generally be applied just above the condyles of the femur. In the method pursued in France, there is certainly the advantage of a longer lever, which is a consideration of importance at the time of the coaptation. For instance, after extension has been made in a sufficient degree, frequently, the next object is to get the head of the bone over the projecting margin of the articular cavity, as is the case in reducing dislocations of the hip; at this moment, by inclining the ankle inwards, and rotating the thigh outwards, you do this with great effect, and very much through the aid of a long lever. When, as is sometimes the case, there is no shortening of the limb, extension beyond a certain point would rather prevent reduction than promote it. Therefore, after you have made extension in a case of dislocation of the hip, and when your object is to raise the head of the femur over the margin of the acetabulum, you do this by making the bone itself, or the whole limb, the lever to be acted on; and, as far as my experience goes, those surgeons are always the most skilful in reducing dislocations, who employ the limb as a lever for inclining the head of the bone into its proper place. This principle I should say is as important as that of relaxing the most powerful muscles of the part. No doubt you ought to relax the muscles, whose action constitutes the chief impediment to the reduction; but you must not overlook the principle of making the limb a lever for bringing the head of the bone back into its right situation. If you can relax the muscles of the limb, and at the same time attend to this principle, you may be sure you are carrying into effect two things of the greatest utility for the accomplishment of the reduction.

In dislocations of the hip-joint, there is another reason why you should employ the limb, or the thigh-bone, as a lever, in reducing the head of the bone; you have to raise the head of the femur over a high ridge, and you would

frequently fail in doing this if you did not attend to this principle. Thus, after having made sufficient extension, it will frequently be necessary to apply a bandage below the groin, which will serve as a fulcrum, by which the head of the bone may be lifted into the acetabulum. By means of this bandage, you make some extension in the transverse direction, and raise the head of the bone over the brim of the acetabulum. Unquestionably, however, you should also relax the most powerful muscles, when you can do so without interfering with the principle of the lever: thus when the tibia is dislocated from the astragalus, the reduction would be exceedingly difficult, unless you were to attend to the relaxation of the strong muscles of the calf of the leg; but, as soon as these are relaxed, the reduction may generally be accomplished with the greatest ease.

The extending means may consist either of a towel, a sheet, a tablecloth, or any other strong piece of linen; applied round the limb; however, it is customary to interpose something between the extending cloth, or bandage, and the skin. In France, surgeons generally apply a piece of linen, covered with some emollient ointment, to prevent the integuments from being injured or chafed. In this country, a wet roller is more frequently used, which will not slip like a piece of greasy linen, and is therefore preferable. Sometimes, however, flannel is put round the limb, and occasionally a piece of soft leather is employed.

When the dislocation is of a ginglymoid joint, a very moderate degree of extension and counter-extension is commonly required; for, in such cases, what is termed *coaptation* is the most important part of the surgeon's business, because as soon as he has diminished the pressure of the articular surfaces against one another, (for you remember, that these dislocations are almost always incomplete,) then coaptation becomes the only thing to be aimed at, and it is effected by lateral pressure, made directly on the head of the dislocated bone. But in dislocations of the enarthrosis joints, extension and counter-extension require to be made with more force, the muscles, capable of resistance, being more numerous and powerful.

One invariable maxim in reducing dislocations is, not to make the extension with sudden and considerable violence, but gradually and at the same time steadily and unremittingly. It is safer to tire out the opposition of the muscles by gradually increased uninterrupted force, than by resorting to short efforts of great violence. In this latter practice, you run the risk of producing considerable mischief, you may rupture arteries and veins, you may contuse and injure important nerves, or you may lacerate the soft parts. But, gentlemen, with all these objections, you would gain nothing, for you would have less chance of getting the bone into its place, than by a milder and more judicious plan. The principle, I repeat, then, is to make the extension slowly

and gradually, and at the same unremittingly; for no muscles, however powerful they may be, can resist force thus employed against them beyond a certain time; and they must inevitably become tired out. As soon as the bone slips into the articular cavity, (supposing it has been a dislocation of the shoulder or hip,) the circumstance is made known by a kind of snap; the joint also immediately regains its natural shape, and its functions are restored. These circumstances will inform you that the reduction is complete.

The *second indication*, which is to prevent the bone from slipping out of its place again, and also to give the ligaments the best opportunity of uniting again, is effected by keeping the joint motionless. But this is not the only thing necessary to be understood; you will perceive, when I get further into the subject, that bones can be dislocated only when the limb is in particular positions; thus, the shoulder-joint cannot be dislocated when the arm is close to the side, nor the hip when the knees are kept close together; the jaw, too, cannot be dislocated as long as the mouth remains shut. You must recollect these facts, and act accordingly. After reducing a dislocation of the thigh, you must therefore confine the knees together with a bandage; after reducing a dislocation of the jaw, you must apply the sling, or four-tailed bandage, to prevent the mouth from opening, for otherwise the condyles may slip under the zygoma again. After the reduction of a dislocated shoulder, the fore-arm must be put in a sling, and the humerus kept close to the side by means of a roller. By attending to these directions, you fulfil two great objects, you give the ligaments the best opportunity of re-uniting, and you render the return of the dislocation impossible: be it also recollected, that while the ligaments are not united, the return of a dislocation will happen, from slight causes.

The *third indication*, or the removal of inflammation and swelling, is partly effected by quietude, which is called for also by the second indication. But, when the inflammation is considerable, it may be necessary to employ bleeding and other antiphlogistic means.

You would naturally expect, from the degree of mischief produced by a dislocation, that abscesses would frequently occur, and other serious mischief ensue; but, as I have already told you, that is not the case; the inflammation ordinarily subsides favourably, and indeed in a shorter time than the mischief subsequent to a severe sprain, the effects of which often annoy the patient for a much longer period, than the consequences of a dislocation of a large joint that has been properly treated.

Gentlemen, the next part of the subject will be compound dislocations; and, if you please, I will give the fourth lecture of this week on Friday at six o'clock in the evening, that is, immediately after Dr. Elliotson's lecture. I also hope to be able to deliver four lectures in the ensuing week.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

*At the Meath Hospital, or County of Dublin
Infirmary, Session 1832-33.*

LECTURE X.

*Intermittent Fever—Rheumatism—Hepatic
Abscess.*

GENTLEMEN,—I must crave your indulgence for having omitted my intended lecture on Tuesday last, in consequence of a severe affection of the throat. The hospital is at present so full of interesting and important cases, that I really do not know where to begin;—in fact, I have never witnessed so many examples of singular and acute diseases as we have been employed in treating during the last ten days.

Before I enter into an examination of any of the cases now under treatment, I wish to make a few observations on a case of ague, which has been discharged from our wards a few days since, as it is possible we may not have another example of this disease during the present session. The fact is, that in Dublin, intermittent fever has of late been a complaint of extremely rare occurrence. It is true, that after the great epidemic fever which raged in this country during the year, we had an extraordinary number of ague cases; and it would appear as if the epidemic of continued fever subsided into one of intermittent, and in this way completely disappeared. It was during this period, when ague was so extremely prevalent, that I made an extensive series of clinical experiments, with respect to bleeding in the cold stage of the disease. At present, ague is very rarely met with here; and the majority of cases which come before us are accidental ones. We most commonly find that the patients are Irish labourers, who have been working in the fenny parts of England, and who, on their journey back to this country, are exposed to a great deal of cold, damp, and misery. The case to which your attention is at present directed originated in this way, and was a very well marked and simple example of the disease. The attack was of the most ordinary kind, tertian, and the man exhibited no evidence of visceral disease, except a swelling of the spleen, which quickly subsided, after the paroxysms had been checked by the use of sulphate of quinine. After remaining here for some time, he was dismissed perfectly well.

A few general observations on intermittent fever may not, perhaps, be unacceptable in connexion with this case, and I wish to impress them upon your attention. The first thing I have to remark is, that we know nothing of the causes which determine the periodic nature of this affection; and in the next

place, that our acquaintance with the laws of periodicity is extremely scanty and imperfect. We see the paroxysms of intermittent fever going through particular stages, ceasing and again returning, sometimes occurring every day, sometimes every second day, sometimes every third day; occasionally they come on twice every day; and there are many more varieties. Again, when we come to the treatment, we find that there is no difference in the principles of treatment founded on the varieties of the disease; we treat tertian in the same general manner as we do quotidian or quartan. The next thing which is to be remarked is, that the treatment of pure intermittent fever must be considered to be empirical. It however exhibits a very remarkable example of what may be termed the most favourable instance of specificism, for we have medicines which will cure a fit of ague, as, for instance, bark. But are we to expect to cure every case of ague with bark?—Are we to consider this disease as affording an exception to the general law, that the true practice of medicine is to be founded on our knowledge of the condition of the viscera?—No. Although we are empirics with respect to the administration of sulphate of quinine, we must be judicious ones: it is necessary for us to have correct ideas on the subject of the viscera that suffer during the paroxysms. I regret to say that too many practitioners take no cognisance whatever of the state of the viscera in this disease; and, no matter whether they be congested, or inflamed, or otherwise obstructed, they go on recklessly “*throwing in*” their specifics; and, when bark fails, they try arsenic, and when arsenic makes matters worse, they go to mercury; and I have known cases where, to make assurance doubly sure, the three remedies were combined. All this time some important viscus was in a state of chronic or sub-acute inflammation, aggravated by each paroxysm, neglected by the practitioner, and exasperated by the “*remedies*.” Some think that it is the spleen which is principally engaged, and have no other idea of the disease. It is true that engorgement of the spleen is of common occurrence, and its enlargement sometimes enormous. A gentleman, who is now present, has mentioned to me that, during a residence in India, he has witnessed actual mortification of the viscera, produced by the pressure of an excessively tumefied spleen. This I can fully believe. It has been stated, that in some cases of ague, which occurred in South America, the splenic engorgement has actually produced hernia of the intestines. But the reason why attention has been chiefly directed to the spleen is, because its disorganisations are very readily noticed; it is composed of an erectile tissue, capable of very great distension; it appears to have a very intimate connexion with the state of the abdominal and general circulation; and hence, during the cold stage of an ague, we can frequently de-

fect a large tumour in its situation. But when we come to consider the subject more accurately, we find that not only the spleen, but also the brain, lungs, liver, kidneys, and mucous membrane of the intestines are all engaged. How are they engaged?—Is the morbid condition of the viscera primary or secondary?—I think we are to look on it as secondary. What do we observe during a paroxysm of ague?—Observe a patient in the cold stage of an intermittent, his face is contracted, his skin pale, the superficial veins appear obliterated, he has a general feeling of coldness, every thing denotes the retreat of blood from the surface of the body. Direct your attention, in the next place, to the condition of the viscera. You find, perhaps, evidence of congestion in the head, the brain is oppressed, and the patient is delirious; you find the chest affected, the cough and difficulty of respiration are often very great, the intestinal tube and liver are frequently engaged, diarrhoea comes on, and there is a copious flow of pale urine, as in hysteria. When we look to the condition of the spleen, we find it rapidly enlarged; we observe too that old ulcers on the surface are frequently dried up, and old vascularities become pale. This circumstance leads us to consider the affection of the viscera as secondary to some primary morbid influence. When the hot fit comes on, a new train of phenomena demands our attention. Nature now makes an effort, and the balance of the circulation is restored. What do we now perceive? The skin becomes hot, the pulse full and strong, the external veins swelled, the face congested, the whole surface of the body regains its vitality, and in proportion as this process goes on, the oppression of the viscera subsides, the breathing becomes easy, the delirium vanishes, the symptoms of abdominal irritation disappear, every thing is relieved, and the patient is free from disease until the next attack. As far, therefore, as the symptoms of ague go, the cold fit seems to produce the retreat of blood from the surface and its determination to the viscera, the hot fit the contrary, and this appears to be the true state of the case.

But our knowledge on this subject does not depend on the inferences we are able to deduce from an accurate consideration of symptoms, we have direct proofs from pathology. When a person dies in the cold stage of ague, we find engorgements of the viscera of the three great cavities. You can conceive, then, gentlemen, how a mild but protracted attack of intermittent fever may produce chronic, and a violent one acute inflammation of various organs. After the cold stage, re-action comes on; the heart's action is increased, and inflammation may be set up in the engorged viscera. It is in this way that we frequently have acute inflammation supervening on ague in hot countries, and chronic diseases in more temperate climates. You may read in Bailly's work, several cases of violent inflammation,

coming on after ague in Italy. In other cases, apoplectic effusions occurred. Rupture of the spleen and liver has also been observed from the violence of the congestion. *You will find that the more healthy the viscera are and the more free from engorgement, the more certain and unequivocal will be the favourable operation of the bark.* It is in those cases where there is inflammation or intense congestion of the viscera present, that bark is found to prove inefficacious, and hence it is that I said, that though we were empirics so far as the sulphate of quinine was concerned, still it was necessary that we should be judicious ones, and have a correct idea of the state of the viscera.

Another very important consideration is the following. I am anxious to impress it on you, as I do not find it sufficiently dwelt on in books. *As soon as the viscera which have been secondarily affected become, either from inflammation or congestion, so altered that they interfere with the performance of healthy functions, they become, as it were, new sources of irritation; what was an effect becomes a cause and hence we have two sources of diseased action in the system; one the primary affection, the other the diseased viscus, which by their sympathetic irritations derange the functions of other parts.* Under these circumstances you will constantly observe a resistance to the favourable action of bark and other specifics. The intermission, too, is frequently not complete, and the whole type of the fever irregular. When you observe these phenomena, you may generally conclude that some organic change of importance is going on, and you must endeavour to find it out, and remove the local affection by the ordinary means.

One word more on this subject, and I have done. You have heard of the practice employed by Dr. Mackintosh, of Edinburgh, and you are aware that the plan of treatment which he recommends in ague has been looked upon in the light of a dangerous innovation by several members of the profession, whose maxim seems to be, "moribus antiquis stet Roma." For my part, I feel bound to say, that I think he deserves the warmest thanks of the profession for the publication of his views of fever, as well as his valuable researches on many other important topics connected with practical medicine; and it is but justice to state, that I do not know a more honourable and liberal man, or a better practitioner, than Dr. Mackintosh. I am anxious to make this statement, because some circumstances, which with others might have excited unpleasant feelings, have occurred between him and me with respect to bleeding in the cold stage of intermittent fever. When I began my clinical experiments on this subject, I remarked that the first few cases on which bleeding in the cold stage was tried turned out favourably. A short time after this, having seen Dr. Mackintosh in Edinburgh, I told

him of my success, and in the first volume of his work on the practice of physic, he quoted me as one of those who approved of bleeding in the cold stage. During the course of the next summer, I again tried the experiment on a much larger scale; nearly one hundred cases were treated by bleeding in the cold stage, and from a careful consideration of the results, I found that it was a practice which I could not safely recommend for general adoption. I regret that I did not immediately communicate these facts to Dr. Mackintosh; I neglected informing him of the result of my second experiments, and it unfortunately happened that my statement and Dr. Mackintosh's came out nearly at the same time. The consequence was, that some persons comparing his statement, grounded on my first communication, with that which I published as the result of more extensive inquiry, went so far as to accuse him of misrepresentation. Of this I must acquit him; he never intended to misrepresent my opinions, and his high character is a sufficient guarantee of his being totally incapable of wilful misstatement.

Among the older authors, it was a long established opinion that there were evident proofs of constitutional debility in the cold stage of ague, and that every thing seemed to demand the use of stimulants and contra-indicate depletion. Dr. Mackintosh came to a different conclusion, and asserted that much benefit may be derived from bleeding in the cold stage, and I must allow that *it may be employed with singular advantage in some cases, and that it is not generally attended with bad or dangerous effects.* I tried this plan during the prevalence of a peculiar epidemic, which came on after the occurrence of typhus, and I believe it would not be fair under such circumstances, to draw conclusions from it unfavourable to the practice, *so far as regards sporadic cases of ague.* So far as our experience of the practice at that period went, we were induced to think, that bleeding in the cold stage was not advisable. We found that in some cases where it was used, the type of the fever changed, the patient got two paroxysms a day instead of one, and that which was tertian became quotidian. Now this was bad. We found also that in some cases new visceral inflammation came on after bleeding, frequently with great violence, and one man was carried off by intense pneumonia, with inflammation of the brain. We perceived that recovery was often tedious and protracted, and that the phenomena, which sometimes appeared, bore a very close analogy to those which result from excessive hæmorrhage. In these cases the bleeding was performed more than once. Our impression, therefore, actually was, that (in this epidemic at least) bleeding in the cold stage was to be looked on as an equivocal and hazardous means of cure, and that sulphate of quinine was both safer and better.

Here I wish to contradict an error into which

some persons have fallen, in supposing that Dr. Mackintosh denies the utility of sulphate of quinine. He does not by any means do this; he gives to it its proper share of praise, but he states that, in cases of visceral congestion, it will act much better after a bleeding in the cold stage. In the recent edition of his book, which I look upon as the best work on practical medicine in the language, you will find many communications from practitioners in India, confirmatory of the value of bleeding in the cold stage, and where there is extensive engorgement of vital organs, as frequently occurs in this disease in warm climates, I think it may be the means of saving many lives, and would advise any of you, who go to India, not to omit making trial of it.

Gentlemen, you have observed that we have been trying the efficacy of croton oil frictions in acute rheumatism and other complaints. We intend to continue our experiments. A few words, while on this subject, with respect to clinical experiments. If we look to the present state of British medicine we shall find one fault pervading almost every published communication, namely, the general but culpable propensity of writers to draw general conclusions from the results afforded by a very few cases. You will find in some of our periodicals a line of treatment recommended confidently, on the conclusions derived from a single instance of disease. Now this is ridiculous. Another great fault in some British practitioners, is the *publication of successful cases alone.* But if a man has treated twenty cases successfully, and failed in a hundred, of what use or value is his statement, unless he gives both, and says fairly here is the result of my experiments, here are my successful and here are my unsuccessful cases. The profession can then strike the balance, and draw the proper conclusions.

We are, as I remarked before, making some clinical experiments on croton oil frictions. As far as we have gone our expectations have not been disappointed. You are all aware that, in the cases in which we have employed it, a kind of papular eruption has occurred, and relief to a greater or less extent has been obtained. In the present case it has proved of some service, but you should always bear in mind, that rheumatism is one of those diseases, in which you should be more than ordinarily cautious of the means you employ in removing the inflammatory affection of the joints, by direct applications of a stimulating nature, because there is a great liability to metastasis. This is a case in which you must have a great many observations, and you must be able to show that the disease is not established in any other part, after you have succeeded in removing it from its original seat. I shall say no more upon this subject for the present, as I have not witnessed a sufficient number of cases to allow me to make any general practical inferences. Mr. Bierly has drawn up a report of our experiments, and his impression is, that there is

scarcely any case in which it has been *un- equivocally* and completely successful. In some instances it has removed the pain, in a few the swelling of rheumatism; as far as we have observed it has not been followed by metastasis. I would say, that in acute affections of the joints, the croton oil frictions promise very well. But I do not think that they should be employed until the period for leeching and other direct antiphlogistic treatment has passed by. Our method you know is to rub in from four to six drops of the undiluted oil, with a piece of lint, over the affected joint; by the next day the eruption appears.

I shall now direct your attention to a case in the chronic ward. The patient came into hospital with cough, pain in the right side, and copious expectoration, slightly tinged with blood. On examination, we found a tumour in the region of the liver, the corresponding side was dull on percussion, but the stethoscopic signs of phthisis were absent. A more careful examination was made by Mr. Chute and Mr. Martin on yesterday, and they have come to the conclusion, that it is a case of hepatic abscess, which has opened for itself a passage into the lung. You will, of course, inquire into the grounds for this statement, they are as follows:—Six weeks ago the man was attacked with severe pain in the region of the liver. At the end of three weeks, without any previous symptoms of disease of the lung, he was seized with a sudden fit of coughing, and expectorated a vast quantity of pus, and it was found that, after the cough and expectoration had lasted for some time, *the hepatic tumour decreased considerably in size*. Hence it was concluded that the matter had got through the diaphragm and pleura into the substance of the lung, the adhesions between the layers of the pleura, consequent on inflammation preventing it from bursting into the pleural sac.

The first thing to be observed on this case is, that the opening of an hepatic abscess into the lung is perhaps one of the most favourable terminations of the disease. When it opens in other situations we may certainly have a recovery, but the instances of this taking place after the matter gets into the lung, are so numerous as to warrant us in considering this as one of the most fortunate terminations. Let us inquire what is the mechanism of this process. The inflammation seizes on the diaphragm, gets through it, and reaches the external layer of the pleura, which it next attacks, the two layers of that membrane become united by adhesion round the point of perforation, and the contents of the abscess finally make a passage into the lung, the substance of which becomes partially engorged, and a passage between the hepatic abscess and the larger bronchial tubes is formed. This is one of the advantages derived from the great tendency of the pleura to adhesion. If the contents of the abscess get into the cavity of the pleura we should have an enormous empyema

with pleuritis. But adhesion takes place, the lung is perforated, and we have, as in this case, a *sudden* expectoration of pus.

A great number of such cases have been observed, but very few of the patients have undergone examination with the stethoscope; I have related one in the London Cyclopaedia of Practical Medicine. In the present case, however, besides the symptoms before mentioned, our opinion was borne out by other considerations. The intercostal spaces were not obliterated; the hepatic tumour, also, was still evident. Now, this might be considered an enlarged or a displaced liver; if displaced, it must be in consequence of a vast empyema of the same side: but of the existence of this there was no indication. You remember, that while on the subject of empyema, I remarked, that where we had dulness of sound and absence of the respiratory murmur in the lower and posterior part of the lung, from the pressure of an enlarged liver, when we make the patient take a deep inspiration, the respiration becomes audible. This did not occur in the present case. It is probable that, in a case where hepatic abscess bursts into the lungs, the adhesions which are formed prevent the descent of the lung on that side, and to this source we are to attribute the defective nature of the diagnosis. I recollect having seen a case of abscess on the liver with a double opening. The woman had pain and swelling of the right hypochondrium while she was here, and some time afterwards an evident pointing. She left the hospital about this time, but returned shortly afterwards with a large swelling; like an anthrax, on her side. This was opened by incision, and a vast quantity of pus gushed out. On dressing this one morning, a quantity of air escaped, and on introducing a probe, it seemed to pass in the direction of the diaphragm. We were therefore led to conclude that the hepatic abscess had not only an external opening, but had also passed through the diaphragm and the substance of the lung. On examination, after death, we found that the abscess was not in the substance of the liver, but external to it, and that, from this situation, it had passed through the diaphragm and the substance of the lung. With respect to the case at present before us, all we can do is, to support the man's strength, and produce resolution of the hepatic tumour; in fact, we must treat it as a case of chronic hepatitis.

Connected with this is another interesting case of a pulsating tumour in the abdomen, the subject of which is a woman in the small Fever Ward. I am not going to give any fixed opinions respecting this case. This patient has been described as labouring under dyspeptic symptoms for the last three years. Some time ago she discovered a tumour in the epigastrium, which is accompanied with evident pulsation, increased, as she states, by going up stairs. It made its appearance after the symptoms of the disease of the stomach

had lasted for more than eighteen months. It is about the size of an apple, movable to a certain extent, and communicating to the hand a distinct pulsation, and on applying the stethoscope over it, a loud *bruit de soufflet* is heard. Six months ago she had some vomiting of blood, which continues to occur occasionally, about half an hour after taking food. There is no sign of the existence of any affection of the heart. She has constant watery eructations, and is tormented with flatulence, and has a continual burning pain in the region of the tumour, shooting towards the shoulder and neck. Her tongue is clean; bowels rather confined; urine scanty; pulse generally about 110.

Now, gentlemen, here is the case of a woman who has bad digestion for a period of three years, and whose bowels have scarcely been in a proper state for many years. Three years ago symptoms of evident derangement of the stomach commenced, and eighteen months after a tumour is observed. She has also had vomiting of blood, and came into the hospital with these symptoms and a violent lancinating pain at the epigastrium. Our first question, then, is, what is the nature of this tumour? We have a tumour situated in the epigastrium, with evident pulsation, increased, as she says, by ascending a staircase. The first impression which this would convey to us is, that it is an aneurismal tumour. Is it aneurism? There are many different kinds of pulsations which are evident to the sense of touch, which are not aneurism, as dyspeptic throbbings, palpitations from disease of the heart, and from nervous agitation;—but in these cases we have no tumour. Here we have a manifest swelling; it cannot, therefore, be attributable to any of these causes. Well, what are the causes of pulsating tumours in the abdomen? aneurism of the abdominal aorta or some of its branches, enlargement of the liver, spleen, or pancreas, or disease of the pylorus? Mind, I do not intend to give any decided opinion on this case, but will observe, that the weight of evidence is against the supposition that this tumour is an aneurismal one. In the first place, the swelling has lasted for eighteen months, and was preceded by symptoms of disease in the same situation for nearly two years before the appearance of the tumour. In aneurism of the aorta, after such a length of time, we should expect a stronger pulsation; we should expect to be able to feel it along the back and in the hypochondrium. In the next place, we cannot move aneurismal tumours. In the present case there is a complete difference; the tumour can be pushed deep into the left hypochondrium under the false ribs, and when you detain it in that situation the pulsation ceases; remove your hand, and let it come back to its former position, the pulsation returns. This occurrence, I must observe, took place in two cases of scirrhus of the pylorus, in which the diagnosis was verified by dissection. Another thing is, the *bruit de soufflet*,

which is heard in the recumbent posture, disappears when the woman sits up. This is often the case when a tumour lies on or over the abdominal aorta; when the patient is lying down the *bruit de soufflet* is distinctly heard, but in the erect position it is inaudible. You are aware that *bruit de soufflet* (by change of position) has been put forward, by Dr. Corrigan, as a sign of material importance in the diagnosis of incipient abdominal aneurism. Without making any observation on this case, I shall merely remark, that the present one will be a test of the accuracy of this doctrine; if the woman has aneurism it will be verified, if not it will be rejected. My own impression is, that it is most probably scirrhus of the pylorus. The shape of the tumour is so different from that of an aneurism; its edges are so remarkably distinct; it ceases to pulsate when pressed back into the hypochondrium, and has been preceded by disease of the stomach; it is accompanied by symptoms of scirrhus; and, in fact, has none of the characters of aneurism.

CLINICAL LECTURES

BY DR. MAC ADAM,

Delivered at the South Eastern General Dispensary, Dublin, Session 1832-33.

LECTURE IV.

Pathology and Treatment of Hooping Cough.

GENTLEMEN—I propose to direct your attention this evening to the subject of hooping cough, several cases of which have recently occurred among our dispensary patients. It is an affection that you will be often called upon to treat in private practice, is frequently attended with considerable danger, is almost always tedious and difficult to manage in its course, and not uncommonly presents very serious complications; a knowledge therefore of the phenomena which it exhibits, and of the best mode of treatment, is of considerable importance to the medical practitioner.

I shall first describe the symptoms which characterise its simple form, next allude to the various complications which it may assume, and to some of the different opinions which are held as to the nature of the morbid state on which the phenomena of the disease depend; I shall also give a short history of some cases which we have lately met with among our dispensary patients; and lastly, state what appears to be the most judicious mode of treatment.

Simple hooping cough may be considered as presenting two distinct stages, which may be denominated the *catarrhal* and the *spasmodic*. The first, or catarrhal, presents the symptoms of common bronchitis, and is seldom attended with much fever. The patient may continue for a fortnight or three weeks in this state before the peculiar sonorous respiration

and long continued paroxysms of coughing, characteristic of this disease, become evident; when these appear, the spasmodic stage may be considered as having commenced. The cough consists of a number of short expirations in rapid succession, continued for a much longer time than in bronchitis, by which the air is expelled in great quantity from the lungs. The fit called the *chink* terminates by a full inspiration suddenly made, which, by the air rushing back through the glottis with unusual velocity, gives rise to that peculiar sound denominated the *whoop*, or *back-draught*, after which the fit of coughing is again renewed, and continues in the same manner as before, till a quantity of mucus is expelled from the lungs, or the contents of the stomach are evacuated, which most commonly terminate the paroxysm, and the patient remains free from cough for some time after. During the fits, the face often becomes turgid and purple, and the eye-balls prominent, and the little sufferer, with a forewarning of the attack, clings closely to anything near him. Yet, in the simple form of the disease, the violence is instantly forgotten, and, after deeply panting for breath, the child returns to his amusements, often with a craving for food. These attacks, at first, recur several times each day, being almost always most severe towards evening, but much more so during the night. After a certain time they return only during the morning and evening, and towards the end of the disease, in the evening only. They are frequently attended with hæmorrhage from the nose, and occasionally from the ears or eyelids; and I have, in some cases, observed the viscid ropy phlegm expectorated from the lungs, mixed with blood.

The duration of the disease varies from a few weeks to several months before it terminates; the paroxysms become shorter, lose their peculiar characters, and are attended by an expectoration more decidedly mucous. Sometimes the disease degenerates into a chronic mucous catarrh, with emaciation, and other symptoms resembling those of phthisis. Laennec observes, "that there is more of periodicity in this disease than in catarrhs in general, and that stethoscopic exploration in the intervals only reveals the usual sounds of catarrh, namely, a feeble respiration than natural, or the complete absence of this in certain points, which, however, sound well; purile respiration in other parts; and occasionally a slight sonorous or sibilous mucons rattle. During the fits we only perceive the shock communicated to the chest by the cough and a slight degree of rattle, and also of the respiratory sound in the brief intervals between the coughs; the natural sound of respiration, whether pulmonary or bronchial, being inaudible even in those parts of the lungs which, immediately before and after the paroxysm, give the purile respirations.

The progress of hooping cough is subject to great variety; when severe it may be pro-

tracted to six or seven months. Even after it has wholly ceased, or nearly so, an accidental exposure to cold has occasioned its return; and this may occur, as Dr. Johnson observes, "several weeks after the cough has entirely subsided; and, after a long time, if the patient accidentally catch cold, the cough will often assume the spasmodic character and be accompanied with the whoop." Its latter stages are occasionally attended with convulsions, which may terminate the patient's life when the event is least expected, or pneumonic symptoms may supervene, and the child die with his lungs gorged with blood, or hydrocephalus may occur and the child die in a state of coma. This event might be oftener expected, when we recollect the force with which the blood is driven upon the brain, and how much its return is retarded during a severe fit of coughing.

Hooping cough may also prove fatal by the co-existence of marasmus or infantile fever, in which the child loses its appetite, emaciates rapidly, becomes hectic, and dies apparently from pure exhaustion. These different affections may be complicated with hooping cough, not only in its latter stages but at an early period of the disease, though modifying remarkably its symptoms, and requiring a considerable difference in treatment. They have been much overlooked both by medical writers and practitioners; and the profession is much indebted to Dr. Johnson, of this city, for having pointed out more clearly than any preceding author the importance of attending to these complications of hooping cough, and the symptoms by which they may be recognised; and, as I propose to present some specimens of these complications to your attention this evening, I think I cannot preface the detail of a few cases of this kind better than by recommending to your attention what this distinguished practitioner has said on this point. His observations are extremely valuable, as they are the result of an extensive experience in this disease. Dr. Johnson considers hooping cough as presenting the following varieties: 1st. Simple hooping cough; 2nd. Hooping cough complicated with bronchitis or peripneumony; 3rd. Hooping cough complicated with disordered bowel, or infantile remittent fever; 4th. Hooping cough complicated with convulsions or hydrocephalus. The simple forms of the disease we have already described.

"The pulmonic complication," Dr. Johnson observes, "is accompanied with considerable dyspnoea, which continues during the intervals; the pulse becomes quick, small, and hard; the fits of coughing more frequent and severe; the lips livid; and the extremities show a tendency to become cold; and there is considerable debility. In many cases the cough is nearly suspended, and when it does occur is not accompanied by the usual whoop, and the difficulty of expectoration is greatly increased. The respirations vary from 60 to 100 in a minute, and when they come down

to 40 or 50 the change generally indicates recovery. The stethoscope discovers considerable and permanent wheezing, which is greatest after sleep, or immediately before a paroxysm of coughing, when it progresses to a fatal termination. The dyspnoea increases, stupor and prostration succeed, the cough is suspended, the pulse scarcely perceptible, the extremities cold, and death ensues from accumulation of mucus producing suffocation; or, if the disease takes a favourable turn, the breathing becomes less hurried, the wheezing diminishes, the cough, after being suspended, returns, the fever subsides, the countenance assumes an healthy hue, and quiet sleep succeeds distressing restlessness."

Such are the general symptoms which this variety of hooping cough presents, which I shall now proceed to illustrate by the recital of a case at present under my care. The patient, named Sarah Jane M——, ætat. three years and a half, has been affected six weeks with severe paroxysms of coughing, continuing for a considerable time, and followed by a sonorous whooping inspiration, and the expectoration of a tough viscid mucus; has bled from the nose during the fits, which are occasionally succeeded by vomiting, but neither the epistaxis or vomiting is so frequent at present as it was at the commencement of the attack. Her breathing is a good deal oppressed during the intervals of the coughing, and some sonorous and mucous râle is heard by the stethoscope. Pulse 189, small; skin hot at night; has an exacerbation at about three or four o'clock p. m., and is a good deal disturbed at night, but gets a remission towards morning; tongue clean; no considerable thirst; some slight diarrhoea of whitish stools. She was ordered some small doses of hydrarg. c. cretâ et ipecac., an emetic of tart. antim. at night; a cough mixture, consisting of extract. conii, extract. hyoscyam. aa gr. iss. viii., ipecac. ʒiii., syrup. toltan. ʒiii., aqua ʒiii., a teaspoonful occasionally, and a blister to the chest. Two days after her mother reported that her respiration became much more easy during the night after the operation of the emetic mixture, but now she appears much oppressed, and has frequent violent paroxysms of coughing; the emetic mixture and powders were repeated. The next day I found her very much improved; the blister had risen well, oppression much diminished, and intervals between the paroxysms of coughing longer; she slept well last night without being much disturbed by coughing. The medicines were continued. I visited her for some days successively, during which she continued to mend, and when last I saw her, I considered her quite out of danger, and recommended her removal to the country.

I view this as a case of hooping cough combined with bronchitis, for the following reasons. First, the existence of permanent oppression in the intervals between the paroxysms of coughing conjoined with some

degree of pyrexia, evidenced by the hot skin, quick pulse, and evening exacerbation; and as far as a stethoscopic examination could be instituted, it appeared to confirm this view, as the mucous and sonorous râle were heard, though owing to the restlessness of the patient the stethoscope could not be applied as often or as steadily as I wished. Now, in simple hooping cough there is seldom any oppression between the paroxysms, nor does pyrexia exist. And though the stethoscope may convey to the ear a slight sonorous or mucous râle, it probably would not be quite so decided as it was in our patient. My treatment, therefore, was founded on this view of the case. As the affection had existed some time, and there was a degree of debility present, I did not conceive it expedient to abstract any blood, though at an earlier period, when there is much dyspnoea, I have found the application of leeches to the back of the head attended with the best effects. In this case I ordered an emetic in the evening, with the view of unloading the lungs of the viscid mucus, which is often present in large quantities in hooping cough, the evacuation of which renders the paroxysms less distressing and long continued; and the action of the emetic produced also another good effect, by determining to the surface and allaying the fever. I also gave small doses of ipecac., and hydrarg. c. cretâ, the former to free expectoration, the latter to restore a healthy biliary secretion. The blister was useful as a counter-irritant, and the pectoral mixture with the conium and hyoscyamus was calculated to allay the irritability of the bronchial mucous membrane, and also to relieve the spasm, which appears to be more or less present in this disease. The treatment has been successful; the urgent pectoral symptoms are now nearly removed, and I have considered the patient sufficiently free from any inflammatory state of the lungs to render removal to the country not only safe but advisable.

The next case which appears worthy of notice, was presented by the brother of the patient whose case I have just recited. He became affected with hooping cough about the same time, is aged about eleven years, and presents the following symptoms. He has violent attacks of coughing, followed by whooping, and the expectoration of a yellowish and not very viscid mucus, not unfrequently mixed with blood; respiration short, but not much oppressed, about forty-five in a minute, chiefly performed by the muscles of the thorax; some pain in the middle and both sides of the chest, increased by full inspiration; has sometimes epistaxis after a paroxysm of coughing; coughs more in the day than at night; pulse 114, sharp; tongue a little whitish; bowels natural; vomits after eating on the termination of the next paroxysm of coughing; some slight abdominal tenderness on pressure; exploration by percussion, and the stethoscope gave the following results. Respiration loud

and clear in the upper part of both lungs, and the chest in those parts sounds clear on percussion; respiration nearly inaudible in the lower part of the left chest, which is dull on percussion, and in the posterior part of the same side a muco-crepitous râle is heard; respiration is obscure in lower lobe of right lung, with some sonorous râle and dullness on percussion there. I directed leeches to be applied to both sides the chest and epigastrium, and one grain of calomel and ipecac., every four hours. The next day he was much relieved and the cough mitigated. The powders were continued.

On the following day both sides of the chest sounded much clearer on percussion; respiration audible in most parts of the thorax, but not so distinct in the lower lobe of left lung, in which a faint crepitous râle is heard in one spot, near which the chest is still dull on percussion, and he complains of some pain in this spot, and of a little in the left chest generally, though it is much relieved since the application of the leeches; pulse 102, soft; tongue a little white; respiration easier; bowels affected seven times since yesterday. A blister was applied to the pained side, and one grain of ipecac. was directed to be given every four hours. On the next day this patient was much better, and after some days all pulmonic symptoms, with the exception of the cough, being nearly removed, I recommended his removal to the country along with his sister.

Now this case of hooping cough I conceive to have been complicated with peripneumonia, the existence of which, I think, was clearly indicated by the presence of pain in the chest, affecting that part which was dull on percussion, near which that peculiar rattle, called the crepitus, was heard; probably the corresponding part of the lung was partially hepatised, or at least gorged with blood, as was evidenced by the dullness on percussion, and almost complete absence of the respiratory murmur. The sanguineous expectoration, we know, frequently occurs in peripneumonia, and afforded additional grounds in favour of our diagnosis. It is likely there was also some degree of bronchitis present. Acting on this view of the case, I directed the local abstraction of blood, and small doses of calomel and ipecac., with the object of promoting absorption in the congested lung, and of facilitating expectoration. I would have used the tartar emetic solution in this case, but the abdominal tenderness and frequent vomiting made me suspect the existence of some degree of irritation of the gastro-intestinal mucous membrane. I preferred the ipecac. to the tartar emetic, as I have reason from repeated trials to think, that given in small doses, frequently repeated, it exerts nearly as beneficial an influence on pulmonic inflammation as the latter medicine, without irritating the stomach or bowels so much; the treatment has answered my expectations, as, in a few days

after, the lungs seemed relieved to a great extent of their congested state, and the patient is now nearly recovered.

The next case of hooping cough, illustrative of its complicated forms, occurred in Thomas H., æt. two years, ill six weeks when I first visited him. He is attacked with violent paroxysms of coughing, during which he occasionally bleeds from the nose and ears, and gets black in the face; the coughing is followed by the whooping inspiration, and occasionally terminates by vomiting, generally of the contents of the stomach, and sometimes of a tough viscid phlegm. The paroxysms are worse at night, and become milder towards morning; some oppression in the intervals. Yesterday, was seized suddenly with a fit of screaming and frequent vomiting, with heat of skin, which has continued since. Pulse quick and sharp; pupils contracted, occasional frowning; was very restless during the night, with constant vomiting and screaming towards morning; got stupid and heavy, is now very restless, and appears to suffer pain; tongue clean; has not coughed much this morning; vomited some greenish yellow matter a short time ago; bowels confined; considerable thirst; lost a sister of three months old by hydrocephalus.

Leeches were directed to be applied behind the ears; the head to be shaved, and the temples frequently to be moistened with a mixture of cold water and vinegar, and the following powder to be given every two hours till a full cathartic effect was obtained.

R. Calomel., pulv. scammon., pulv. rhei, $\bar{a}\bar{a}$ gr. xii. *M.* divide in pulv. viii.

The next day I found him much better; bowels had been well opened. The powders were continued.

Two days afterwards he was reported to have passed a restless night, during which he coughed much, and bled from the ears. I ordered him small doses of ipecac. antimonial powders and carbonate of potass, which he continued to use with relief to his cough for some days, and when last I saw him he was free from all urgent symptoms. This case I considered as complicated with a determination of blood to the brain, which probably would have terminated in convulsions or hydrocephalus, if active means had not been used at an early period.

It was evident that the paroxysms of coughing produced a congested state of the blood-vessels of the head, which was indicated by the hæmorrhages from the nose and ears, and the lividity of the face. The sudden accession of a febrile paroxysm, with violent and long continued vomiting, unaccompanied with coated tongue, or any other symptom of gastro-intestinal affection, resembled much the preliminary stage of a hydrocephalic attack; the contracted pupil and the occasional frowning co-existing with these symptoms afforded additional proof of an excited state of the brain;

and the circumstance of a child of the same family having died of hydrocephalus, seemed to render it likely that a predisposition to this disease existed. The success of the treatment, too, favoured this view. If the vomiting and pyrexia had originated from gastro-intestinal irritation, it is not likely that leeches behind the ears would have produced such decided relief, and the active purgative would have aggravated such an affection. From these considerations then I think my diagnosis was correct. The shaving the head, and the application of cold, assisted in diminishing the irritability of the brain, and the combination of antimonial powder, ipecac., and carbonate of potass was calculated, 1st, to relieve the cerebral congestion by the antimonial, which seems to exert a specific influence in determination of blood to the head; and, 2nd, to promote expectoration by the ipecac., in which effect it was assisted by the carbonate of potass, which I have found by experience to promote expectoration in those cases, both of hooping cough and bronchitis, in which a viscid tough mucus is secreted; it appears to render the mucus more fluid and less tenacious; how it does so I do not pretend to explain; but I am satisfied of the fact, as in several cases in which the mucus was of this description, I have found it become more fluid, and more easily brought up by coughing from the exhibition of this medicine.

The complication of hooping cough with infantile remittent fever or disordered bowels, will prevent a combination of the symptoms characteristic of such states with those peculiar to hooping cough. As I have no case at present under my care exactly illustrative of this variety, I consider it unnecessary to enter into any general detail, but beg leave to refer you to the excellent article by Dr. Johnson on hooping cough, in the tenth part of the *Cyclopaedia of Medicine*.

Having thus given you a short view of the symptoms and complications of hooping cough, you may, perhaps, expect that I should say something about the proximate cause of the disease, or that morbid condition of the affected organs, on which the phenomena of the affection depend. This is a subject of very great difficulty, and on which we find a vast diversity of opinion among medical writers. It seems to have been considered as a spasmodic disease by Cullen and several others; Dr. Webster thinks that the seat of hooping cough is in the head, and that the affection of the respiratory organs is only a secondary effect, being an effort of Nature to relieve herself by expanding the lungs to an unusual degree, thereby allowing a greater quantity of blood to flow into them, in order to diminish the fulness and congestion in the head. Some have supposed it to be seated in the phrenic and pneumogastric nerves; others, among whom was Watt and Laennec, thought that it was always an inflammatory condition of the bronchial mucous membrane; Desruelles

supposed it to be at first inflammatory, and afterwards spasmodic; Dr. Dawson conceived it to consist essentially in an inflammation of the glottis of a specific nature, which either remained there, or involved the larynx, trachea, and lungs.

The fact is, its nature is unknown, and it is much more easy to say what it is not than what it is. I think we are justified in concluding, that it is not essentially an affection of the brain, for innumerable cases occur in which there are no symptoms whatever of a cerebral affection, which when it occurs can be satisfactorily explained as an accidental complication. I conceive we are not right in conceiving it to be primarily and solely a spasmodic disease, as its first stage always presents catarrhal symptoms, proving that an irritating cause has been applied to the bronchial membrane, giving rise to increased irritability and increased or altered secretion; but we ought not to conclude that this state amounts in every case to inflammation, as many instances occur in which there are no symptoms of inflammation whatever; perhaps the most probable supposition is that in all cases there is a peculiar irritability of the bronchial mucous membrane, induced by a specific cause, and taking a certain time to exhaust itself; that this irritability may excite spasmodic action, or be kindled into inflammation in predisposed constitutions, or the violence of the paroxysms may cause, in some cases, congestion in the brain, which may give rise to convulsions or hydrocephalus, or hooping cough may co-exist with, or be aggravated by, a deranged stomach or intestinal canal. This appears to me the most practical view we can take of the subject, and I shall not waste your time longer in speculating on such uncertain grounds, but proceed to make some short observations on the general treatment of the disease.

When hooping cough is unattended with any other affection, it will probably run its course without being very much influenced by medicine. Occasional doses of rhubarb and ipecac., or the latter medicine combined with calomel, may be useful; an emetic may also be given whenever there appears any tendency to dyspnoea in the intervals, and the lungs seem oppressed with a quantity of viscid mucus. Dr. Pearson's plan I have tried in some cases with a good effect; he recommends first an antimonial emetic, and afterwards a draught containing a drop or two of tinct. opii, five drops of ipecac. wine, and two grains of carbonate of soda, to be repeated every four hours, for several days; when purgatives are required, he gives rhubarb and calomel. When the disease is on the decline, the cough still continuing without any other affection, antispasmodics and sedatives may be used. When it has become intermittent, accompanied with some debility, the sulphate of quinine has been given with the very best effects. Change of air at this stage is also very useful; but the most important point in the treatment of hooping

cough is to watch closely any tendency to pulmonary inflammation or affections of the head, which we should endeavour to obviate as soon as possible by appropriate means. Venesection, or local bleeding, according to circumstances, should be early employed, and if the lungs are attacked, the tartar emetic solution, and calomel should be exhibited.

Purgatives should be freely administered; but Dr. Johnson observes "that continued purging will be found to produce a degree of flatulence which by the pressure of the distended intestines against the diaphragm, will increase the dyspnoea, irritate the mucous membrane, and needlessly debilitate; and that when the bowels are very irritable, so as to preclude the use of ipecac. or antimony, we must chiefly rely upon the use of the lancet, blistering, the warm bath, and small doses of nitre." After effusion into the bronchia and air cells has taken place, the doctor cautions us against the further abstraction of blood, as by increasing the debility, we might diminish the expectoration; in this stage repeated blistering, calomel, and ipecac., and occasional emetics of tartrate of antimony, or in very young children, ipecac. wine and syrup of squills, will be of advantage, and the hydrarg. c. creta may be substituted for calomel if the bowels are irritable. Having mentioned blistering, I think it of some value to the junior practitioner to be aware of the caution to be observed in its application to infants and young children. Many patients of this class have suffered unnecessary and protracted torture, and have even lost their lives by the injudicious use of these remedies, while I am satisfied, from my own experience, that they may be applied with perfect safety, even to very young infants, under proper restrictions; the great danger arises from leaving them on too long. It should be recollected that a blister will produce as much effect on the tender and irritable skin of a young child in one or two hours, as it would do on an adult in twelve. Acting on this principle, I have always been in the habit of directing the attendants to examine the surface to which the blister is applied in such patients, *one hour afterwards*, and if the skin appeared decidedly reddened, *not to wait for vesication*, but to take off the blister instantly and apply the usual dressing, and I have generally found that vesication took place afterwards; but if the surface appeared unchanged, to replace the blister and carefully to inspect it every half hour or hour till the rubefacient effect was produced. This rule I think of great importance. I have known infants lose their lives in consequence of a blister being left on eight or twelve hours, and I have known others that finally recovered, suffer for weeks from an extensive ulcerated surface, attended with great constitutional irritation, and only saved by the greatest care. This caution I would wish particularly to impress on your attention as applicable to all cases in which blisters are used in infantine diseases.

When whooping cough is complicated with convulsions, we should investigate their cause; if connected with dentition, we should employ the treatment suitable to such cases; if from irritation of the bowels, change of diet or nurse may be necessary; sometimes change of air puts a stop to their recurrence. If affection of the brain is the cause, hydrocephalus is to be apprehended, which is observed to be more than usually fatal when it occurs in conjunction with whooping cough. The treatment suitable to idiopathic hydrocephalus should be promptly employed, which it is not necessary for me to detail, as it has been already fully considered here not very long ago.

When whooping cough is complicated with deranged bowels or infantile remittent, the treatment suitable for such cases is to be employed in conjunction with that which we have before detailed as proper in simple whooping cough; antimonial emetics, however, are to be avoided, as they would be likely to aggravate the excited state of the gastro-intestinal mucous membrane. I shall not, however, detain you by entering into the consideration of the treatment of this combination, as what you have already heard relative to infantile remittent, applies equally to this form of the disease.

The cases to which I have endeavoured to direct your attention this evening illustrate points of considerable practical importance, and afford a striking proof of the value of dispensary clinical instruction, such cases not being likely to be presented to a student's attention in an hospital where patients affected with whooping cough, are rarely, if ever, admitted. I do not recollect to have seen one case of the kind during my hospital attendance while a medical student, and consequently I had no opportunity of forming a practical acquaintance with the disease during that period of my professional life. In fact, this is common with many other affections, can only be studied extensively by the student in dispensary practice. I trust the time will yet arrive, when the profession will duly appreciate the advantages which such institutions afford, not only as a means of relief to the physical ills of a numerous portion of suffering fellow-creatures, but also as an abundant source of practical information to the medical and surgical student.

ON THE OIL OF THE CROTON TIGLIUM AS A PURGATIVE FOR CHILDREN.

BY EDWARD AUGUSTUS CORY,

Member of the Royal College of Surgeons of London, Surgeon to the East London Lying-in Institution and Dispensary for the Diseases of Women and Children, &c. &c.

It is a matter of the greatest importance, in the treatment of the diseases of children, that the remedial agents

employed should be palatable to the patient. A disease is frequently aggravated considerably by the forcible administration of nauseous medicine, especially where the head and chest are affected; indeed, this remark will apply to the generality of inflammatory affections. It is well known, that the active principle of the cathartics, usually administered to children, is calomel, it being the least unpleasant to the taste; but this remedy I am convinced, from multiplied experience, does not completely answer the required end, unless it be given in combination with other aperients, as jalap, rhubarb, &c. &c., which render it extremely disagreeable to the little patient. One of the most pleasant and efficient purgatives for children, with which I am acquainted, is the ol. croton., prescribed according to the following formula:—

R. *Olei crotonis*, gtt. ij.
Sacch. albi, ʒij.
Pulv. acaciae, ʒss.
Tinct. card. co., ʒss.
Aq. q. s. ft. mist., ʒiiss.

Of this a child, five or six years old, may take two or three teaspoonfuls every three or four hours, until the bowels have been freely acted upon. I have been for some time in the daily habit of using this preparation in the treatment of the diseases of children, where a complete and speedy evacuation of the bowels is required. I have found it of admirable service as a purgative in cephalic and thoracic affections; it acts with great celerity, and occasionally produces a gentle vomiting, which is often salutary. I do not recollect one single instance where its action has been violent and dangerous, when given according to the formula directed. I strongly recommend its general use, and I feel confident that it will become a favourite medicine in all the morbid affections of children, where a quick, certain, active, and pleasant purgative is indicated. It may be proper to remark, that the croton oil I prescribe is procured from, and, I believe, prepared by, Messrs. Drew, Heyward,

and Baiss, wholesale druggists, Great Trinity-lane, Bread-street. It appears to be of excellent quality.

Cannon-street Road,
 St. George's East,
 July 17, 1833.

PRIZE ESSAY,

PROPOSED BY THE MEDICAL REFORM ASSOCIATION,

For the three best Essays on the following subject. Three prizes are offered.

SUBJECT.

“On the present state of the Medical Science and Practice* in the United Kingdom, and the most advisable and efficient mode of promoting the advancement and the improvement of both in all their branches.”

For the *best* Essay will be awarded the sum of £50 sterling.

For the *second*, the sum of £30.

For the *third*, the sum of £20.

CONDITIONS.

- I. The competition is open to *all* persons, whether of the medical profession or not, and the award will be made in *public*.
- II. The Essays are to be written in the English, French, or Latin languages, and these only.
- III. They must be transmitted to Dr. Epps, 89, Great Russell-street, Bloomsbury, London, on or before the 1st day of March, 1834.
- IV. They must be clearly and neatly written, and *not* in the handwriting of the authors.
- V. Each Essay is to bear a motto, and to be accompanied by a sealed letter, with a corresponding motto to that inscribed upon the Essay. Within the sealed letter there must be the name and place of residence of the author.
- VI. None of the letters will be opened but those connected with the mottos of the success-

* These comprise *medical statistics*.

ful essays; and the unsuccessful essays will be delivered, upon satisfactory reference, by Dr. Epps, the Hon. Secretary. The Prize Essays will be returned to their accredited authors, who may, if they think proper, publish them for their own advantage, or otherwise they will be published by the Association.

Signed by order of the Association.
JOHN EPPS, M. D. Hon. Sec.

N. B. One hundred pounds, the amount of the three prizes, are already lodged with the treasurer, Joseph Hume, Esq. M.P., who, with the other judges, will *publicly* deliver the several sums, as they shall be awarded to the successful candidates. The names of the other adjudicators will be published at a future and not distant period.

J. E.

WRIGHT ON CARDIAC PATHOLOGY.

Carditis and pericarditis—suppurative, chronic.

FERDINAND GIBBS, a black man, about thirty years of age, admitted into the Baltimore Alms-house, December, 1831. This man was above the middle size, person well-formed and muscular, exhibiting the appearance of a vigorous organic system, but little impaired by sickness or former disease. There was no emaciation, nor any manifest constitutional derangement or chronic malady. The symptoms on admission were those of ordinary febrile catarrh, or what is usually called a bad cold; patient had cough, hard, and somewhat frequent, attended by soreness in the breast, and slight hoarseness; no fixed pain in the chest, nor any palpable impediment to free inspiration; cough not sensibly excited or exasperated by deep breathing. Fever was moderate; pulse about 90, full and soft, no discoverable irregularity; temperature nearly natural. Patient represented his cough to be more fre-

quent and harassing when lying down than in sitting, standing, or walking about; present indisposition reported to have existed about two weeks. Diagnosis—subacute inflammation of the sero-cellular tissues of the thorax, in other words, serous pneumonia, or catarrh.

Treatment.—Rest in bed, low diet, antimonials, and an epispaic in front of the chest. On the third day in hospital, patient was nearly free of fever; said he was well enough to be up, and solicited permission to leave his bed, and also indulgence in stronger diet. Permission was granted to be out of bed, but with orders to remain in hospital; diet regimen continued as before; medicine omitted. In the night of the following day, the fourth after admission, this man, without unusual complaint, or being known to have been more unwell than common, was discovered about midnight in a state of insensibility, and rapidly sinking. Respiration was short and sonorous; surface cold; pulse extinct; limbs relaxed. He died in a few minutes after being discovered in the state described.

Examination.—On opening the thorax, the portion of the mediastinum immediately under the sternum presented appearances of recent inflammation in a moderate degree; cellular tissues tinged red, and slightly infiltrated with lymph matter. The upper anterior surface of both lungs was also marked by superficial phlogosis; serous covering of the lungs redder than natural. The substance of the lungs was every where soft and pliant, without signs of condensation, or other evidence of altered state or texture.

The pericardium was excessively dilated, occupying all the middle space of the thorax, pressing the lungs aside, and forcing them high into the superior regions of the chest. This great bag contained a fluid, which proved on incision to be matter of a light yellow colour and uniform consistence, exhibiting the qualities belonging to what is called laudable

pus. The quantity of matter contained in the pericardium was supposed to exceed one gallon; much of it was effused into the cavity of the thorax at the moment of incision, yet enough was collected to fill a common tin wash-basin. The interior of the pericardium, and the surface of the heart, were somewhat roughened by flocculent lymph, though not otherwise unnatural in appearance or condition; there was no excess or intensity of colour upon those surfaces indicating acute or recent phlegmasia. The heart itself was of the ordinary size.

Remarks.—This case strongly exemplifies the possibility of severe phlegmasial action on the surface of the heart, without serious embarrassment of its special office as the principal organ of circulation; the centre and salient point of the distributive system. There was here no palpable manifestation of impeded action of the heart, nor any appreciable defect of full and regular supply of the important material of excitement and nutrition to all the organic systems. The man neither acknowledged nor betrayed any feeling or sign, importing imperfection or incapacity of circulatory power. He was not affected with labour, hurry, or shortness of breathing; he had no pain in the region of the heart; no distress of countenance; no coldness of the surface, nor any infiltration of the lower extremities, or of the cellular tissue in other parts of the body; position of body was not known to produce any symptoms referable to interruption or disadvantage of action by the heart; although cough was provoked or increased by lying down, yet there was no particular sense of oppression in this posture, nor greater inability to lie on one side than on the other. The pulse was free, moderately full, and not discoverably unequal or irregular; not sensibly altered by change of posture; no sudden failing of its force or evenness by muscular efforts; no tumult or flutter of movement

under the circumstances, and no tendency to collapse or syncope; the man walked about the ward with apparent ease on the day preceding his sudden death.

The most remarkable phenomenon in this case, is the complete nutrition of the body, which had been maintained under chronic disease, so serious in kind and degree, affecting the main organ of supply, for all the material of growth and repair of parts. It was manifest that the immense collection of pus in the bag of the heart was no late or sudden accumulation. Its formation was a work of time, and had commenced long before his late sickness, but when, or under what circumstances, could not be determined. The patient's account of himself went no further back than the date of his recent illness by cold, about two weeks prior to admission, and there was nothing in his appearance or symptoms to induce inquiry concerning his state of health at a more remote period. He had the external (personal) marks of a sound condition of all the important organs, and it is curious how this fact could have consisted with the state of things revealed by examination.—*American Journal of the Medical Sciences.*

CASE OF SCARLATINA MALIGNA SUCCESSFULLY TREATED BY COLD WATER.

BY SAMUEL JACKSON, M.D., OF NORTHUMBERLAND, U. S.

(Communicated in a Letter to the Editor.)

My oldest daughter, of eleven years, was, a few weeks ago, seized with cynanche maligna, with far more fever than usually attends that malady. Her fauces were universally inflamed, and on the second day the cineritious specks appeared. I bled her in the height of the evening paroxysm to eight or ten ounces, though I knew that the fever was certainly typhus, with the pulse 160. But the difficulty with me consisted in the choice of gargles. From some experience and much contemplation last fall, I

had fixed my mind on sac. sat. as the most proper *till* sloughing might take place.

To this then I resorted, but quickly became dissatisfied, lest she might swallow so much as to cause lead colic. The nitrate of silver was then tried, twenty-four grains to the ounce of water. From this I had some hope, derived partly from the Medical Reporter, vol. xiii. p. 123, and partly from the known effects of a milder solution in ophthalmia. But I soon became dissatisfied with the use of a stimulus to parts so highly inflamed, notwithstanding all that has been said in favour of stimuli in these cases. My anxiety on this point became excessive; for I was possessed of the opinion that on the speedy improvement of the local disease depended the fate of my child. I had lately seen cases successfully treated by my friend, Dr. Vanvolsap, of Lewisburgh, eight miles above us, by means of stimulating gargles, particularly the capsicum, but I could not prevail on myself to use them till further mortification might reduce the inflammatory action.

Cold water she desired above all things, and I determined to give it a fair trial. She was then permitted to drink the coldest ice water, and to hold ice in her mouth. But this last experiment was dangerous, lest she might swallow it, and bring on spasms of the stomach. It was then inclosed in a gauze bag, and put far into her mouth to be dissolved and swallowed. Now, for the first time, the fourth day of her disease, I felt satisfied with my prescriptions, and she was desired to use the ice freely, and to drink largely of ice water. The good effects were immediate, surprising, incredible, and almost divine. Within a few hours the pulse was reduced from 160 to 120, the circumscribed crimson disappeared from her cheeks, the extremities became warmer as the fauces and stomach were cooled, the whole countenance was changed, the typhus distress left it, and something of the vivacity of common fever supervened.

No other remedy was thenceforward used, except some laxatives; and in three days from the time the ice was tried, there was no fever left, nor any sign of inflammation in the fauces.

The disease was, last fall, epidemic, a few miles above us, and some died. One of my other children had it in the course of the winter, but very slightly; and, as I hope to have no further need of this remedy, and can give it no further trials at present, I commit it to your consideration. I have just heard that scarlatina cynanchica is mortal in your city; and, as this is certainly the same disease as the cynanche maligna, I hope you will give my remedy whatever attention it may seem to merit, independent of what little I have done. — *Ibid.*

BEAUTIES OF MEDICAL EVIDENCE.

York Assizes, Wednesday 17th.

DEATH BY PRIZE FIGHTING.

DECEASED had been drinking the evening before the fight; the contest continued for an hour, when both fell, the deceased undermost. He was raised, and on going forward to meet his opponent fell forward as if shot.

The medical witnesses differed as to the cause of death. Some held it was produced by spontaneous apoplexy, brought on by his exertions to win the fight; and the others, that the external violence contributed to produce the fatal result. The jury returned a verdict of guilty.

In a trial at the Hereford Assizes, 11th instant, the surgeon swore that the cerebral congestion was caused by mental emotion, and that the blows had nothing to do in causing death. The judge told the jury, that this evidence acquitted the prisoner. Verdict not guilty. In this case there was considerable extravasation of blood under the scalp; and had we been the witness, we certainly should not have said, that the blows had nothing to do in causing death. The

discrepancy of medical evidence has long been remarkable, and can easily be accounted for by the utter neglect of medical jurisprudence until the present period.

THE

London Medical & Surgical Journal

Saturday, August 3, 1833.

THE ASSOCIATION FOR MEDICAL REFORM.

IT appears by an article in a preceding page of this number, that three prizes are offered, for the first, second, and third best essays on the state of medical science and practice in the United Kingdom, and on the best mode of promoting and advancing both. It is a matter of great gratification to us to observe this notification, as it is the strongest proof that can be given, of the determination of medical reformers to effect the grand object they have in view, which has long been a subject of deep interest to us. We rejoice that reform in all our existing medical corporations is inevitable, and that the noble science of medicine will no longer be impeded by the bad policy of the self-interested junta, who have hitherto so effectually retarded its progress. It must be admitted by all, that the London College of Physicians have wofully neglected the interests of science and the public. They were, and are the source, the fountain-head, of all abuses in the profession, the *fons et origo malorum medicorum*. They have very nearly abolished the once respected name of physician, by shutting their portals in the face of every

man of science and erudition, unless he was educated at Oxford or Cambridge, where the medical schools are universally acknowledged to be the most defective in Europe. In proof of our accusation against the College, we adduce the following evidence from their report laid before parliament on the 16th ult., in which it appears, that since 1771 to 1832, there were admitted into the College 169 Fellows, and 117 Licentiates since 1823.—Behold the 169 Physicians of England during a period of 61 years!!! The College of Surgeons have admitted, during the last 33 years, about 12000 members, and the Apothecaries, since 1815, about 6000; so that the practice of medicine in England is very nearly in the hands of surgeons and apothecaries; while the members of the College of Physicians are almost “an atom in the vortex of infinity.” Such is the result of the by-laws of the London College of Physicians. Can any lover of his country or science view this degraded state of medicine, in the greatest and most scientific nation on earth, without feelings of disgust and scorn for those who have effected it? Can any one, unless interested in existing abuses, who is aware that in all other countries physicians are proportioned to the wants of the public, advocate the baneful policy of the College? If there be such a man in the profession, we pity him. In Ireland and in Scotland, the proportion of physicians is comparatively greater than in this section of the kingdom, though the by-laws of the Colleges

of Physicians in both are based upon those we denounce. In France, Germany, Italy, and America, physicians are much more numerous than surgeons and apothecaries; and the practice of medicine, or the safety of the public health, is committed to those who, by superior education and medical erudition, are best qualified to preserve it. In England, as we have already said, the public health is committed to persons who assume the rights of physicians, whose general and scientific knowledge is of a very inferior description; and this crying evil is effected by the London and other Colleges of Physicians.

If physicians be declared useless, then let them be abolished at once. If they who must receive a good general and classical education—who reside at universities for four years—whose minds are enlarged by the blessings of general and medical knowledge—whose college associations are the most respectable—if they, we say, be not better qualified to undertake the awful duties of saving human life, abridging human suffering, and acting more politely towards the sick, than those whose early education has been neglected, whose medical knowledge is far less extensive,—then let them be suppressed.

To us it appears certain, that the legislature of this kingdom will never consent to suppress a learned profession, however zealous a few of its interested members may have been to effect it. We are, moreover, convinced that the by-laws of all the Colleges of Physicians in the United Kingdom

will be annulled by the next parliament, and that the scientific will be rendered entitled to equal rights and privileges. We have also reason to know, that the physicians of this empire will be raised to the rank and station awarded to them by various parliaments, and that others who now encroach upon them will be confined to their proper province. It would be foolish to suppose that the church and law should be subjected to salutary reforms, and the remainder of the learned professions be left unchanged, though replete with as much corruption and gross abuse as the former.

Mature consideration has long since led us to the conclusion, that any reform must benefit all ranks in the profession, promote their interests, and be of service to humanity. Our honest and anxious wish is, that all classes of our brethren should be benefited, and that the lives and health of our fellow-creatures should be protected and preserved. Whatever may be supposed to the contrary, we feel the self gratification that our endeavours were and are intended for the good of humanity and science, and that they have hitherto been directed against the abuses in all our medical institutions. Our strictures and animadversions have given offence to the short-sighted, narrow-minded, and self-interested; but our motto was and ever will be—“*salus populi suprema lex esto.*” We attack all delinquents; we show their hideous deformity, and the fatal consequences of their selfish policy; and we prove to all of them, that the spirit of the

age is against them. Our sincere desire is, that the profession of medicine in all its branches should be as perfect in this as in other countries; that it should shed its benign influence over society, and that it should promote human happiness. We desire to see all medical practitioners esteemed by the public, and that pure science be exerted for the relief of disease. All philanthropists are with us, and if we be in error we are in good company.

OBSERVATIONS ON LOCAL BLOOD-
LETTING, AND ON SOME NEW
METHODS OF PRACTISING IT.

BY JONATHAN OSBORNE, M.D., &c. &c.

OPENING the veins of the foot is a practice still resorted to in cases of obstructed menstruation by practitioners who must be above the influence of vulgar prejudice on the subject. The trials which I have made have not enabled me to arrive at a conclusion as to the question whether this practice possesses any advantage above general blood-letting. Bleeding from the veins of the tongue is another old practice now nearly forgotten, having been superseded by the more manageable mode of taking blood by leeches. By opening the veins on the back of the hands we can usually obtain blood with great facility when particular circumstances forbid bleeding in the arm. Bleeding from the jugular vein is not well suited for taking blood from the head, because the external jugular, which alone is within our reach, is supplied from the superficial veins of the neck, and principally from those of the larynx, but not from the interior of the head. Great benefit, however, may be derived from opening it in sudden attacks of croup.

The application of leeches is frequently a cause of great fatigue to the patient, from the length of time

during which stupor with hot water is kept up in order to promote the hæmorrhage from the leech bites; and, in some cases, when this operation is continued under the bed-clothes, the damp communicated to these produces cold, and is uncomfortable to that degree as often to prohibit their use. All this is obviated by the application of warm cloths of linen or calico applied perfectly dry, and removed in succession according as they have become saturated. By these means the blood is absorbed by capillary attraction, a process which cannot take place with wet applications. When dry cloths are thus applied and renewed to cuts in the skin, or to leech bites, I have found the bleeding uniformly to continue as long as the application was kept up, it being required only to supply fresh portions of the dry cloth to insure the continuance of capillary attraction, and thus to prevent coagulation at the mouths of the vessels.

This mode of managing leeches I am thus particular in describing, as it has enabled me to apply them in a case in which, if wet cloths were used, very serious danger might arise. I allude to bronchitis, both acute and chronic, in which the application of leeches to the larynx and to the trachea in the triangular space between the mastoid muscles, has appeared to me to be the most decisive and immediately successful remedy of all those which I have ever employed. In laryngitis, their utility is obvious and commonly recognised, but in bronchitis it has escaped notice, that the most immediate depletory process which can be performed on the mucous membrane of the bronchial tubes is that of leeching the trachea and larynx. It appears to remove blood not only from the mucous membrane of that part of the bronchial tube to which the application is made, but also from the whole tract of the bronchial tubes throughout their ramifications, being nearly equally efficacious in putting an end to the cough, when the remoter tubes are affected, as when the

larynx is the chief seat of disease. This application is also of singular efficacy in stopping the cough of phthisis, insomuch, that by resorting to it according as required in cases in the hospital, we have been enabled to secure sleep at night, and during the day to keep the phthysical patients so free from cough, that a superficial observer might readily believe that we had cured the disease.

It has been ascertained that leeches will continue to live and to draw blood, although immersed in water at a temperature considerably above 100°. Now, in cases of violent inflammation of the abdominal viscera, when local abstraction of blood and warm fomentations are both at the same time imperatively demanded, as soon as leeches have been applied to the abdomen the patient may immediately be placed in a hip bath, without waiting for them to fall off. Thus we may cause the relaxation and diminution of sensibility produced by the heat to combine with the benefit to be derived from the topical loss of blood.

The application of leeches to mucous surfaces was, I believe, first described by the Surgeon-General, Mr. Crampton. Although I have not met with any case of cynanche which required the direct application of leeches as advised by him, yet there can be no doubt as to the immediate benefit to be derived from it. I have resorted to the mode of applying leeches to other mucous membranes by passing a needle and thread through their tails, at about one-fourth of an inch from the extremity. This practice, so far from incapacitating them from action, causes them to bite with increased ardour, and, in fact, may be used to stimulate torpid leeches. The thread to be passed through the tail of the leech should be strong, and its extremities are to be held by the operator, while, if necessary, he may direct the mouth of the leech by a probe, or channel made with a card, to the place where its services are required.

In certain headaches confined to the frontal sinus, which, although originally derived from derangements of the digestive organs, yet do not cease when those derangements have been removed, a prompt relief is obtained from applying leeches in this manner to the interior of the nostrils; and in those cases no benefit is usually derived from leeches externally applied. The bleeding is usually rather more copious than if the application had been made on the skin; if, however, it should be deficient, the patient may encourage it by breathing over the vapour of hot water.

In inflammations of the conjunctiva, a leech thus applied to the Schneiderian membrane of the adjacent nostril evidently unloads the vessels of the eye. This application I have found of great use after the previous application of leeches to the tarsal conjunctiva. It appeared to render the improvement derived from the latter permanent, and prevented the necessity of repeating it.

In inflammations of the ear, this mode of applying a leech inside the meatus is eminently useful; and next to it in importance is the application of them behind the ear as near as may be to the meatus. It may be objected, that such applications are not well suited to inflammations of the internal parts of the ear, inasmuch as those are supplied by a different set of vessels from the external. But the effect of leeches is independent of vascular connexion. For example:—in inflammations of the stomach or intestinal canal, the benefit derived from leeches applied to the corresponding region of the abdomen is acknowledged by all; but the vascular connexion between those parts is as remote as that between distant regions of the body, the one being supplied from the arteries arising from the abdominal aorta, and the other from the epigastric and mammary arteries; and that there can be no anastomosis of vessels is evident from the interposition of the peritoneum, which insulates the viscera completely

from the anterior parietes of the abdomen. The same observation applies with the same force to the thoracic viscera and to the brain. In all those cases, however, the effect of local bleeding is proved so repeatedly in our daily experience, that the inability of satisfactorily explaining the way in which the effect is produced must not be allowed for one moment to press against the evidence of facts.

In inflammation of the mucous membranes of the bowels, especially of the rectum, the French practitioners apply leeches to the margin of the anus. If the leeches take externally, no benefit is derived, and to apply them internally is often difficult, on account of the violent contractions of the sphincter. Those contractions also prevent any considerable quantity of blood being obtained from the bites. I have employed a method of taking blood from the rectum which obviates these inconveniences.—*Dub. Med. Journal.*

HÔPITAL DES VENERIENS.

(Original Report.)

Remarks on Tonsillar, Sublingual, and Anal Ulcers.

BY ALEX. THOMSON, M.B. OF ST. JOHN'S CAMB.

(Continued from p. 732, Vol. III.)

Mercury, its effects in this case.

FIRST of all, during its use, he had no uneasiness in the bowels, no nausea, no vomiting, and no interruption in, no augmentation of, and no change whatever in the period of, his alvine evacuations, save on the 27th of April, when he had his healthy, but liquid stools, and a deficit rather than an increase in the quantity of the saliva. Then, after nine grains, the gums were slightly affected, continued so for two days, and then got well without the mercury being left off, or any change being made in his regime. Lastly, the ulcers certainly did not tend towards cicatrisation in the slightest degree previously to the administration of the mercury; but the

anal ulcers began to do so, and more rapidly cicatrised, immediately after its commencement. Three days after its commencement, the lingual ulcers began to change in aspect; and six days after the commencement of its use all the ulcers of the mouth and throat began to cicatrise, and for four days went on cicatrising with extraordinary rapidity, while the pulse remained reduced in number to 66, and until the end of those four days, when the mouth became affected, and most of them were cicatrised; the remainder cicatrising slowly during five days, and the mouth regaining its natural state without the mercury being discontinued. Hence it appears that the system was affected by the mercury, that the ulcers profited by that influence, but that the remainder were retarded in their cure the moment that influence became too great. Yet this evidence, though apparently strong in favour of the mercury, is not perfect, inasmuch as we cannot determine what was the influence of the sarsaparilla.

Anal Ulcers, their progress.

April 13th. The ulcers of the anus are two in number, situated on the circumference of the anus, with elevated, indurated edges of a bluish-red hue, and regular margins, having both a hard base, a greyish-yellow, flat, even bottom, yielding little matter, a bluish-red areola of one line in breadth, and their long diameters parallel to the axis of the rectum; one placed in the anterior median line of the rectal orifice, one-sixth of an inch long by one-eighth broad, and ascending from the margin of the anus into the rectum; the other, one-fourth of an inch long by one-sixth broad, descending from the left margin of the anus, at about three lines from whence it commences.

14th. Wash the anal sores from time to time with decoction of linseed. Touch them both with nitrate of silver.

15th and 16th. Unchanged.

17th. M. Ricard has examined with

me this morning the anal ulcers, and admits their perfect similarity, in all the external characters, with chancre, but maintains that they are not chancres on account of the inoculation not having taken. He calls them ulcerated mucous pustules, simulating chancres.

18th. The anal ulcers are much improved; the anterior one is three-fourths cicatrised, its edges are less elevated, and the bluish-red areola is gone; the lateral has also lost its areola and the reddish-blue line of its edges, and is fully one half cicatrised. He has taken but one grain of proto-ioduret of mercury, and that yesterday.

19th. The anal ulcers are all but cicatrised, and of a pale reddish-blue hue, and on a level with the skin.

20th. The anal ulcers both cicatrised, of the same colour as the surrounding skin, the anterior a little bluish in the centre, and the lateral covered in the middle with a thin yellowish-brown crust, both round, notwithstanding their original oval form; each about one-sixth of an inch in diameter, the edges being still more elevated and harder than the middle of the cicatrices, though similar in colour to the skin.

21st. The anal ulcers perfectly healed, with firm cicatrices, the crusts having fallen from the middle of the lateral ulcer.

Anal Ulcers, their nature.

Such are the ulcers on the anus, having, indeed, all the external characters of chancre, but doubtful in their origin, having, if the man is to be believed, already been cured by mercurial ointment, and broken out again simultaneously, with an increase of all the symptoms supposed to be secondary, and having commenced at the same time with ulcers on the glands and the secondary sores of the tongue and tonsils. Yet the matter of these ulcers being inoculated into three places with great care produced no pustule, and as yet, during a three

months' and a half course of experiments under M. Ricard, at the Venereal Hospital of Paris, I have never seen the matter of chancre fail of producing, on the first inoculation, the characteristic pustules. The inference was natural, and M. Ricard decided that they were not chancres. Yet we are thus reduced to admit either that there are sores having all the external characters of the chancres on the anus, contracted by anal connexion, that are not really chancres, or that all chancres will not produce, on inoculation of their matter, the characteristic, or indeed any, pustule.

Anal ulcers.—To what may their cure be attributed?

It is remarkable, that in spite of the linseed-tea wash, in spite of the touch on the 14th with the nitrate of silver, these sores were in no way changed in external characters until the 18th, four days after the cauterisation, fifteen days after they were first seen, and the first day after the commencement of the use of the proto-ioduret of mercury, of which only one grain had yet been given; yet on this day they were on a sudden more than half cured, although one can scarcely believe that the mercury had as yet affected the system, and in three days afterwards were entirely healed. One simple hot bath of an hour's duration, the day after the cauterisation, half nourishment, honeyed barley-water for drink, with a pint of milk daily, and repose in bed, are the only remedies that can have produced any previous effect. It would appear, therefore, that the mercury may have hastened but could scarcely have had any direct action in commencing the healing of these ulcers, and therefore that ulcers having all the external characters of chancres, without yielding the inoculatory pustule, may be cicatrised during the use of anti-phlogistic means alone.

Indolent Tumour diminishing the capacity of the Pharynx, unaccompanied with annoyance to the Patient.

There was in this case a remarkable affection of the right side of the pharynx, where, without the posterior palatine pillar being displaced, the space between its free edge, and the median line of the vertebral surface of the pharynx was occupied by a hard substance with a flat surface, which when touched by the finger, was hard, resistant, solid, and not painful or tender, having its surface even, and covered with healthy looking mucous membrane, and producing no swelling externally, apparently permanent, extending as high and as low in the pharynx as the eye could examine, unmoved by the different movements of the pharynx, unproductive of the slightest annoyance, unchanged in consistence and form during the course of the treatment, and capable of presenting a very serious obstacle to the performing of tonsillar excision, whether by the straight bistoury or the newly invented tonsillar scissors of Cloquet. I have seen another tumour similar to this in every respect, and like it unchanged during the course of the treatment in another case of secondary symptoms.

Tonsillar Ulcers, their progress.

They were both unchanged from the 3rd to the 13th of April.

13th. The tonsils are both prominent one or two lines beyond the free margin of the palatine pillars, occupied entirely each by an ulcer, of which the circumference is regular and the edges hard, abruptly elevated, and about one line in prominence, and the bottom of the ulcers uniform, or nearly so, and red, with some spots of pus and mucus mingled here and there, having each about three quarters of an inch in vertical, and half an inch in antero-posterior diameter. The right ulcer is already

in part cicatrised along the middle of its anterior edge.

14th to 29th. Unchanged. He began the use of the proto-ioduret in doses of one grain a day on the 17th, with the sarsaparilla drink.

21st. The right tonsillar ulcer retains its elevated edges, as though the ulcer were still open, but these edges are soft, and the whole ulcer with them is covered with a thin epiderm.

22nd to 24th. Unchanged.

25th. The elevated edge of the right tonsillar cicatrix gradually diminishing towards its natural level.

The left tonsillary ulcer is much diminished, has its bottom covered with moderately red granulations and a little mucous pus, its edges much less elevated, and much diminished in thickness, the anterior having become attached to the body of the gland. The ulcer itself is still two thirds of an inch in vertical by one third in horizontal diameter.

26th. The elevated edges of the left tonsillar ulcer sunk to a level with the surface of the gland, in the lower half of which they are adherent, and which is itself cicatrised to that extent, smooth, and covered with an unpuckered and smooth membrane.

27th. The posterior upper fourth of the left tonsillar ulcer remains now uncicatrised and with slightly elevated edges, the anterior of the upper fourth having assumed the same appearance with the lower half.

28th and 29th. Unchanged. 30th. Unseen. 31st. Unchanged.

June 1st. The remainder of the left tonsil is now covered with an epithelium, thin, but smooth, regular and unpuckered, although the posterior edge of the ulcer is not as yet sunk to a level with the body of the gland. He leaves the hospital as cured.

Remarks on the nature, progress, and cure of these Tonsillar Ulcers.

These ulcers had, it appears, been the results of a fortnight's uneasiness,

came on at the same time with the sores of the tongue, after kissing or licking the parts of his mistress; differed from most of the tonsillar ulcers I have seen referred to secondary symptoms, in not having their bottom flat, and of a greyish yellow hue, or their edges, as it were, gnawed, or sharply cut; yet M. Ricard considered them as such, and they were remarkable by their uniform symmetry and by the unequal manner in which they were influenced by the treatment. The right remained nineteen days in the same state, and then was suddenly in twenty-four hours perfectly cicatrised, its edges remaining elevated for five days afterwards, and then rapidly sinking to its natural level, so as in two or three days to be no longer perceptible. The left, notwithstanding the symmetrical appearance, did not change in aspect for four days after the cicatrization of the right, progressed much more slowly, went on cicatrising for three days, remained with the upper fourth alone uncicatrised and stationary for four more days, and then was suddenly closed in twenty-four hours. In the left, the swelling of the edges diminished gradually opposite to the parts cicatrised and immediately subsequently to their cicatrization. Neither of the ulcers had in the slightest degree changed in aspect by the simple or opiated marsh mallow gargle, nor by the half nourishment, the repose in bed, or the barley-water drink, until such time as the mercury had been administered. Four grains only of the proto-ioduret had been taken on four successive days with the sarsaparilla drink previously to the sudden healing of the right ulcer. Eight grains, with the same drink, had been taken on as many successive days, previously to any change occurring in the left, and fifteen grains before the termination of the cicatrization of the same. It is to be remarked, that the healing of the right and the commencement of that of the left both took place before the mouth was affected, the

former five days, and the latter one day previously. The left went on rapidly cicatrising during the four days anterior to the mouth's becoming sore, and during which the pulse was reduced to 66, and then when the mouth became affected, remained stationary for four days until the soreness of the mouth had ceased, and then became suddenly healed in twenty-four hours.

THE LONDON UNIVERSITY CHARTER.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—The London University is looked upon by every well-wisher to the education of the people with delight. It is an antagonist that is about to try its strength with Oxford and Cambridge, and other universities, based upon the exclusive principle, admitting none to their honours but upon the presumed safeguard of a particular creed. The giant will prevail, if so be that he be not manacled by the chains prepared by exclusiveness. The proposed charter will be either the developer or the destroyer of his glorious manhood. If made upon the liberal principle, so that *all* can apply to be admitted to collegiate honours of the university, *no matter at what school, or at what place* educated, the London University will be glorious in its majesty; but if the exclusive principle is acted upon, and all, save those few *who have been educated within the walls of the university*, are to be excluded from sharing in the collegiate honours, then the London University will be an object of disgust to every friend to freedom in science, and to every hater of monopoly.

This leads me, gentlemen, to express my astonishment that the private lecturers of London (and let it be remembered that the most scientific lecturers of the London University *were* and *are* still private lecturers), do not meet to present a memorial to his Majesty's ministers on this point.

That a charter will be granted to the London University I have every reason to know; and, therefore, exhort private lecturers, not simply for the sake of themselves, but for the sake of the University itself, and also for the sake of the principle of *universality*, boasted of by scientific men, to meet and to prepare a memorial embracing the points specified.

Believe me, Gentlemen,

Yours truly,

London, July 24th. MEDICUS.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Compression of the Brain—Trephining.

WILLIAM BOWKER, ætat. five years, was brought into this hospital on the 21st July, having fallen from a height of six feet on a stone pavement.

On his admission to the hospital, he was perfectly insensible; pulse very small; pupil dilated; severe contusion of the scalp, and fracture of the parietal bone of the right side.

He was placed under Mr. Brodie's care.

23rd July.—*Sub. Mur. Hydrarg.* gr. ii;
Pulv. Rhei. gr. viii;
V. S. ad. 3ii.

The patient has been bled several times, and Mr. Brodie found it necessary to remove part of the bone on Saturday last.

30th July. Patient is unusually heavy this day, and appears quite unaffected by external agents; eyes heavy and fixed. Bowels have been moved last night.

Sloughing of the Penis—Retention of Urine.

Wm. Mallett was admitted into the hospital on the 21st July, he complained of inability to evacuate urine. On examination, it appeared that the entire glans and a considerable portion of the penis had, in consequence of former disease, sloughed

away, and about an inch only of the penis remained. The orifice of the stump, owing to the neglect of the patient, gradually diminished in extent and became nearly obliterated, in consequence of which, inability to pass urine ensued. Mr. Brodie has introduced the catheter several times, and the patient is rapidly getting better.

Simple and Compound Fracture of the Leg — Amputation — Convulsions after Hæmorrhage.

Wm. Lovett was brought into this hospital on Saturday night, a wagon wheel having gone over his leg some hours before his admission.

There was dreadful contusion of the integuments and fracture of the tibia of the right leg. There was simple fracture of the left leg. The patient seemed to suffer great agony during Sunday, and mortification of the right leg set in. The leg, from the patella downwards, was exceedingly cold, while the temperature of the rest of the body was increased.

Mr. Hawkins, under whose care the patient is, proposed amputation of the limb on Monday, to which the patient consented.

Mr. Hawkins then proceeded immediately to amputate the leg. During the operation the patient fell into violent spasms, and sixty drops of laudanum were administered. Whilst the surgery porters were in the act of carrying him down stairs a jet of blood was discovered issuing from the stump; the patient was instantly conveyed back to the operating theatre, when Mr. Hawkins having removed the bandages soon discovered the bleeding artery and passed a ligature round it. The patient is now doing well.

Danger of Leaden Bougies.

Mr. Brodie, whilst going round the wards the other day, took occasion to remark that he disapproved of the employment of leaden bougies, which, he said, were objectionable, as *not* being sufficiently flexible to adapt themselves properly to the curve of

the urethra, and being, in some cases, liable to be broken. Mr. Brodie has known five cases in which leaden bougies broke in the bladder.

Fungous Excrescence—Amputation of the Leg.

On Thursday, the 25th of July, Mr. Babington performed amputation of the leg for fungous excrescence of the tibia.

ST. BARTHOLOMEW'S HOSPITAL.

Fracture of the Leg—Delirium—Death.

James Hickey, ætat. 35, was conveyed in great agony to this hospital on the 8th of July, his leg being fractured in a fall while quarreling.

On his admittance his leg was set; but in a few days he became delirious, and knocked off the splints, so that it was deemed proper to bind him with straps to his bed. About midnight, however, by an extraordinary effort, he succeeded in breaking the bands, and having got up he threatened to murder all the inmates of the ward. He struck, with a wooden bar, two of the porters. Being at last secured, he was strapped tightly to his bed. On Thursday, the 25th of July, he died furiously delirious.

French Medicine.

Syphilis repeatedly communicated to the same Individual while under Cure.

M. RICARD, surgeon to the Hôpital des Veneriens at Paris, read a memoir before the Royal Academy of Medicine, June 4, in which he stated that an individual, affected with syphilis, may contract other chancres, both before and during the ordinary treatment. He also maintained that secondary symptoms are not contagious.—*Archives Gén. de Médecine Journ. Complémentaire des Sciences Med., Juin.*

[This last conclusion is generally

admitted, though we consider it erroneous. We should ask its advocates,—How does it happen that a parent labouring under this form or stage, communicates it to the fœtus in utero? There is no general rule in medicine without an exception.—Eds.]

Abolition of Quarantine in France.

At the meeting of the Academy of Sciences on the 8th instant, at which were present MM. Gay-Lussac, Thenard, Magendie, Double, Serres, it was the general opinion that quarantine was *absurd*, and that it was France that should give the impulsion for its first abolition. What will our quondam friends at Whitehall say to this? Every one of them may shake his innocent head, and declare—"thou canst not say I did it." Neither does the world accuse you.

At the meeting on the 9th instant M. Pariset delivered an eulogy on Cuvier, whose bust was placed in the Academy.

Monomania in relation to Legal Medicine.

M. Marc read a memoir, in which he maintained, that all the works on mental alienation produced nothing but sterility, inasmuch as they offered the explication by reasoning, without taking into account organic lesions, and that the classification was formed upon vicious and uncertain bases. He blamed many of his countrymen, and concluded by announcing that he would speedily communicate new facts with regard to incendiary monomania, and that by mutation.—*Journ. Univ. et Hebdom., Juillet.*

Case in which several Biliary Calculi were discharged outwardly from an Abscess.

A man, aged forty-eight, applied at La Charité for advice, respecting a swelling which made its appearance several months before, at the lower edge of the false ribs on the right side. It was accompanied with con-

stant severe pain; but there was neither vomiting, nor any symptom of jaundice; diarrhoea had occurred at intervals. The swelling, at first very painful and hard, became gradually softer; an eschar was formed by rubbing caustic potass on its surface; and when this separated, a considerable quantity of reddish purulent matter escaped. The pains however did not abate. This state of things continued for upwards of five months, the purulent discharge going, on all this time, when the patient felt as if some rough or pointed body was irritating the wound in the side. One of his companions drew it away by means of scissors; and after its removal, a copious flow of pus followed, with great relief to the pain and general distress. On the recurrence of these, he applied at La Charité, and now it was ascertained that the substance which had been withdrawn was a biliary calculus; it was of the size of a pea. Upon probing the wound, the point of the stylet came in contact with something hard, rough; and moveable; when extracted it proved to be another biliary calculus. Fortunately the constitutional disturbance was not great; there was considerable emaciation, but the appetite was good, the bowels regular and healthy, and the pus from the wound laudable.

During the subsequent week several calculi were discharged, and the patient improved in every respect. Cases similar to the one now reported have been recorded by various authors, as Petit, Scemmering, Cheselden, &c. &c. Those who are interested to know the particulars are referred to the paper in the March number of the *Archiv. Générales*.

Alum as a Remedy for Cancer.

M. Guneau de Mussey speaks in terms of confidence of the efficacy of alum in cancerous diseases. After describing a peculiar pain in the feet, which he has noticed as a characteristic and distinctive symptom of cancer of the womb, he states, that

he has cured an enlargement of the prostate by the internal administration of alum in the doses of eight to sixteen grains. He has likewise employed with advantage, in cases of cancerous breasts, a solution of alum, with a little camphorated spirit. In some cases of gastralgia this means has been found beneficial.—*Jour. de Chim. Méd.*

Instrument for extracting Substances from the Bladder.

M. Segalas has invented a new instrument for extracting from the bladder any long, thin, supple body, such as pieces of a bougie or catheter. This instrument consists of a piece of wire, divided up half its length by three branches, whose extremities are unequally bent towards a centre. This wire is sheathed in a bent canula, slightly flattened, which serves as a conductor and constrictor; a screw is so attached as to effect a gradual and firm movement backwards.—*Ibid.*

Indian Medicine.

Indian Ophthalmia treated with much success with Alum.

M. SONTY, in a report which he lately made to the Minister of the French Marine, mentions his great success in the treatment of a most violent and rapidly destructive epidemic—purulent ophthalmia, in the East Indies. At first he had employed antiphlogistic measures, but they entirely failed, or rather the disease was too intense to be quickly enough affected by them. The natives employed very stimulating applications; as, for example, a mixture of pepper, lemon-juice, and the juice of tamarind leaves, to which is added afterwards, roasted walnuts; this paste they applied round the eyelids. M. Sonty soon found out the marvellously good effects of rock alum. He took a piece, with which he kept stirring, for eight or ten minutes, the white of an egg, which is then to be put into a fine muslin bag.

When this is to be used, the patient's head must be held back, and while the eyelids are kept open, a few drops of the liquid are to be squeezed from the bag upon the eye. This operation must be repeated very frequently, —in some cases every half hour. The same treatment is applicable in all the stages of the disease, and generally cures it in from 24 to 48 hours. —*Archiv. Génér.*

German Medicine.

Tic Douloureux cured by Stramonium.

OBS. BY DR. FOTT.

A YOUNG lady, who had suffered for several years from tic douloureux, which sometimes terminated in swelling of the cheek, or by swelling of the lip of the affected jaw, had tried a great number of remedies without any benefit. The author cured her in the space of six weeks by an issue in the arm, and by giving her internally from eight to fifteen drops of tincture of stramonium every third hour. —*Beitragte Mecklenburgischer Aerzte, B. 1, H. 2.*

Peculiar Treatment of a Chronic Vomiting.

BY DR. FOTT.

A woman of plethoric habit, not very muscular, but whose appearance seemed to indicate florid health, had suffered for nearly fourteen years from gastralgia and enteralgia, and had not been a single day without vomiting during that space of time. Every known remedy had been tried, and especially anthelmintics, without any success. M. Fott, thinking the disease to be a nervous affection, or probably rheumatism, of the stomach and intestines, prescribed the hydrocyanic water of Schrader, in the dose of seven drops every third hour. The patient soon found herself relieved: she went out in a coach without vomiting, which she had not done for fourteen years. The vomiting, which disappeared for three days, returned on the fourth, continued for several

days, and then suddenly ceased. It was succeeded by cedematous swelling of the legs and thighs, which yielded to the exhibition of calomel, united with yellow sulphur of antimony, opium, and digitalis, with frictions of oil of sweet almonds and henbane. The vomiting did not return for three months, when the patient brought it on again by the immoderate use of curdled milk, and by affections of the mind. The hydrocyanic water did not succeed this time: M. Fott prescribed a mixture composed of tincture of opium, half an ounce; Hoffman's anodyne liquor, two drachms; chamomile infusion, eight ounces: a tablespoonful to be taken every two hours. The vomitings ceased, and did not return more than once in two or three weeks: it finally yielded to the use of this mixture. —*Ibid.*

Spontaneous Cure of Hydrocele in the space of a few Hours.

BY DR. KRIMER.

A labourer, aged 52, was affected with hydrocele for some years. A puncture had been made, when a pound of serous fluid had been discharged, and the testicles were found in a healthful state; at the end of three weeks the serosity began to accumulate anew in the tunica vaginalis. Nine months afterwards, the patient applied to Dr. Krimer; the tumour was then the size of a child's head. M. Krimer proposed to effect a radical cure by the incision and excision of the vaginal tunic, to which the patient consented. On the day appointed for the operation, Dr. Krimer went to the patient's house with some of his colleagues, and was very much surprised at not finding any traces of the hydrocele. The patient stated, that the evening before, having raised with great exertion a weight of near 200 pounds, he felt in the inguinal region that something had given way, with violent pain, as if his abdomen was torn; he went to bed, after having passed a great deal of urine; and when he awoke he perceived the disappearance of the tumour, and the

existence of an ecchymosis, which extended on the left side of the scrotum. The spermatic cord and epididymis were varicose, the inguinal ring closed, and neither fluid nor pain remained. Fomentations with vinegar and water for three days, and with wine and alum for six days afterwards, removed the ecchymosis, and diminished the varicosities of the spermatic cord. — *Medicinisches Conversationsblatt*, No. 14.

Extirpation of a diseased Ovary.

A. D., aged 31, mother of four children; during her last, the fifth, gestation, the abdomen was so enormously distended, that it was thought that she was pregnant of twins. The size, however, was not much abated after delivery, and it was then ascertained that it was caused by an enlarged ovary on the right side. A trocar was introduced, and fourteen pounds of a serosity were drawn off; the limits of the swelling could now be more easily defined; and, as it felt hard and fluctuating, the trocar was inserted at another point, and twelve pounds more of a watery fluid were evacuated. Dr. Ehrhartstein decided on its extirpation, which was performed eighteen weeks after delivery.

On exposing freely the diseased mass, it was found to have contracted adhesions to the surrounding parts; these were cautiously severed, and the tumour extracted in fifteen minutes from the commencement of the operation. Only three vessels required ligatures. Several febrile symptoms supervened, and lasted for several days. On the eighth day a profuse discharge of bloody serum and of gas escaped from the wound, with great relief to the patient. In nine weeks the wound had healed completely.

The diseased ovary weighed twelve pounds, and when cut through exhibited numerous cavities, partly filled with a serosity. The three vessels which had been divided were of the size of writing quills. — *Med. Jahr. des Oester Staats*.

MALIGNANT CHOLERA.

We are grieved to state that we have attended six cases of cholera since Saturday, in all of which there was blueness; in some, the diarrhoea ceased, in others, the vomiting. Three of these were saved by the following remedies:

R. *Mist. cretæ* 3vj.; *t. catechu* 3j.; *t. opii* 3j.; *sp. am. arom.* 3ij.-iiij.; *ol. menth. pip.* ℥v.; *ext. hæmatoxyli* 3ij.; *dosis* 3ss. *omni quadrante horæ*.

When the diarrhoea was arrested, ʒj. of hyd. subm. was given every three hours; and 3j. of ung. hyd. fort. rubbed into each axilla every half hour until ptialism was produced.

CORRESPONDENTS.

J. T. is unreasonable.

H. B.—We shall be happy to receive impartial reports of interesting cases.

Dr. Veitch shall hear from us by letter.

Mr. H.—The speech on Medical Reform is admirable, but too long for insertion in a Medical Journal.

Mr. G.—The Liverpool Medical Journal is bold, judicious, and independent. It appears monthly.

A Reformer will see by this Number that his ideas are anticipated.

T. A.—This plan of reform is too sweeping. We withhold it, as the writer may enlarge it, and present it for the prizes offered by the Reform Association, announced in the present Number.

Mr. W. of Birmingham.—We are much obliged by the punctuality with which the promise was performed. We regret the unjust and unmerited prejudice on the part of the individual alluded to, and we could effectually remove it, if he be a reasonable person.

Bristolensis.—We cannot re-advert to the subject.

J. M., E. F., J. W., J. T., *Chirurgus, Medicus, &c.*—The Lectures shall appear at our earliest convenience.

Mr. S.—We wish the promised lectures as early as corrected by the able Professor.

Subscriptions received in aid of liquidating DR. RYAN'S law expenses incurred in defending the respectability of the Profession, amounting to nearly £1000 . . . £229 2 6

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XLVIII., DELIVERED FEB. 6, 1833.

GENTLEMEN,—The severity and danger of *compound dislocations* depend upon various circumstances; as first, *upon the size of the joint concerned*; a consideration, however, more applicable to compound than to simple dislocations; for I have already explained, that in simple dislocations the size of the joint affects the prognosis but little, and that some simple dislocations of the thumb are more difficult to reduce than those of the shoulder. But, in compound dislocations, the size of the joint makes a great difference in the degree of severity and danger of the accident. In the second place, *the size of the wound or laceration in the synovial membrane, and the extent of injury in the ligaments and tendons*, are circumstances making a material difference in the seriousness of a compound dislocation. Thus, when the wound in the synovial membrane is large, and the joint of a considerable size, like the knee, the accident may be regarded as one of urgency and peril. Thirdly, *the danger will also depend, in some measure, on the degree of mischief done to the soft parts near the joint*, as the contusion or laceration of the skin and muscles. Fourthly, *several kinds of complications may add to the severity of the case*: thus, a dislocation may be complicated with a fracture and comminution of the bone; a dislocation may be attended with a rupture of an artery or vein of magnitude; and experience proves, that this occurrence, though rare, is possible in dislocations of the shoulder. The same accident may also be complicated with paralysis of the

arm from pressure of the head of the humerus on the axillary plexus of nerves, an affection sometimes difficult to cure.

Compound dislocations of the ankle are perhaps more frequent than those of any other joint in the body, and the greater number of them are at the same time complicated with a fracture, especially of the fibula. Compound dislocations of the thumb sometimes become complicated with tetanus; and hence a few practitioners have gone so far as to advise, in such cases, the immediate amputation of the injured part, as a means of preventing that fatal disorder; but the propriety of this advice I cannot admit as a common rule.

Compound dislocations are treated much on the same principles as compound fractures. In the first place, you have to decide whether the condition of the limb will justify the attempt to save it or not. This question must be solved by reference to various points already specified. If the joint be of a considerable size, like that of the knee, and the synovial membrane be extensively torn, and the soft parts a good deal injured, then of course your duty will be to perform immediate amputation. Compound dislocations of the elbow, ankle, and wrist, will not often require amputation, unless the soft parts are very considerably injured; they are found to need amputation in a fewer number of instances than were operated upon about thirty years ago; in fact, such accidents usually terminate well, unless they are accompanied by an extraordinary degree of laceration and contusion of the skin and muscles, and also with fracture, as happens in bad gun-shot wounds, or from the passage of a heavy carriage over a joint. When an attempt is to be made to save the limb, you must act nearly in the same way as in a compound fracture, that is, you must endeavour to convert the compound dislocation as quickly as possible into a simple one, by doing all in your power to unite the wound by the first intention. Examples are met with, in which the head of the bone protrudes through the skin, and a great difficulty is sometimes experienced in returning it. Under these cir-

VOL. IV.

circumstances, some surgeons prefer sawing off the head of the bone to making violent attempts to reduce it; and you will find, that Mr. Hey, in his Observations on Surgery, relates a few cases in support of this practice. The only thing, I believe, that can warrant the plan of sawing off the head of the bone when it protrudes, is the impossibility of reducing it by any other means; for you will find that, in the cases related by Mr. Hey, the patients never regained a complete use of the limbs which had been so treated: and probably they limped, and walked less perfectly than they would have done if the head of the bone had not been sawn off. At all events, this is the impression made on my mind by the perusal of the cases in question.

After having accomplished the reduction of a compound dislocation, the first thing then is to procure union of the wound by the first intention if possible, and thus to convert the compound dislocation, as it were, into a simple one that has been reduced. Afterwards, gentlemen, you should endeavour to prevent the inflammation from advancing to a violent height; for you will find, that in compound dislocations, the inflammation which follows them, especially when the wound has not united by the first intention, is always disposed to be severe. On this account you should employ cold evaporating lotions, leeches, and even venesection, together with other antiphlogistic measures, particularly quietude of the joint and limb. Sometimes the inflammation and swelling are so great, that you cannot employ splints immediately; but, unless the objection to them on this ground is well founded, they should not be omitted, for they prevent motion of the joint, and give the torn ligaments the best opportunity of uniting again.

The amputation of limbs for compound dislocations, as I have said, is less frequently performed now than in former days; and you will find, gentlemen, after the dislocation is reduced and the wound dressed, that the appearance of the limb is much altered for the better, and the case loses all at once its terrific aspect. Indeed, the success of the practice of attempting to save the limb in the greater number of instances of compound dislocations, which formerly would have been thought to require amputation, is now so encouraging, that I may truly say, that where six cases were formerly considered to demand the operation, there is now only one. However, it must not be concealed, that examples do present themselves, in which amputation is necessary; and in these, if you are certain that the operation cannot ultimately be avoided, it is best to amputate at once; for if you lose the present opportunity, inflammation, followed by fever and violent constitutional disorder, will come on, and you will perhaps never have again a favourable moment for the operation. In fact, the same rule is here applicable as in severe compound fractures and bad gun-shot wounds, and which, you may

recollect, I particularly called your attention to when those subjects were before us, namely, that when a limb is obviously, from the first, incapable of being saved, it is best not to defer amputation, but to take the earliest opportunity, as the very best which can be had, of performing the operation.

I come next, gentlemen, to the consideration of *particular dislocations*; and first I will describe those of the lower jaw.

Dislocations of the lower jaw.—It is evident, that, so long as the mouth is shut, nothing can dislocate the lower jaw; but when the teeth are separated, and the mouth wide open, the condyles pass forwards on the eminentiæ articulares; and while they are in this position, if there should be any spasmodic action of the depressors of the chin, or of the external pterygoid muscle, to incline them a little more forwards, they will slip under the zygomatic processes, and thus a dislocation will be produced. The condyles of the lower jaw can be dislocated in no other direction, than that forwards under the zygoma, and the accident may happen either in the manner I have described, or in consequence of some external violence acting upon the body of the bone, at a time when the mouth is open. In fact, at that period, a very slight force applied, so as to depress the chin, will force the condyles to glide under the zygomas; and hence, dentists, when they are rough and careless in their proceedings for the extraction of the teeth, may dislocate the lower jaw.

I have said, that the dislocation can only take place forwards under the zygoma; and this is true with respect to the two kinds of dislocation to which the lower jaw is liable; one of which is that in which both the condyles are displaced, and the other the particular case where only one of them is dislocated, which is less common, but sometimes happens, one condyle being thrown under the zygoma, while the other continues in its proper place. I should explain to you, however, that the lower jaw is subject to another kind of accident, attended with a partial displacement of it, namely, the case in which the condyle of one side slips out of the inter-articular cartilage; this is called a *subluxation of the jaw*; the condyle does not quit the capsule, but merely the inter-articular cartilage, the jaw becomes motionless, and the mouth continues slightly open. But all those dislocations, in which the condyle quits the capsule, take place in the manner, and in the direction, which I have explained. You meet, then, with three cases, the *dislocation of both condyles*, the *dislocation of one*, and the *subluxation* of the lower jaw, or mere displacement of one condyle from the inter-articular cartilage.

With respect to the symptoms of a complete dislocation of the lower jaw, I wish you to observe, gentlemen, that in consequence of the position assumed by the bone, when the condyles are thrown forwards out of their

articular cavities, the mouth must necessarily remain open,—it cannot be closed; for this would be prevented by the coronoid processes touching the cheek bone; I need scarcely tell you, then, that the power of speech will be considerably impaired. After the bone has remained unreduced for some time, it is true, the mouth will become rather less widely open; but still it cannot be closed, on account of the mechanical impediment to which I have just alluded. The chin is considerably lengthened, and the lower teeth, if they could be brought up as high as the upper ones, would be much in advance of them. In consequence of the irritation of the parotid gland, there is a profuse secretion of saliva, which is incessantly dribbling out of the patient's mouth. The nature of the accident, I think, gentlemen, must be obvious enough from the circumstances already enumerated.

When the case is a dislocation of only one condyle, you may observe, particularly in thin persons, a slight distortion of the chin or mouth, an inclination of it towards the opposite side; but in fat subjects, this kind of deformity will be so slight, as perhaps not to be noticed. Mr. Hey has made some remarks upon this symptom, which is not always so manifest, but that it may not attract observation. When both condyles are dislocated, there is one symptom worth remembering, which is, that, in consequence of the chin being elongated, the cheeks are always stretched out, so as to have a much flatter sunken appearance than what is natural. After the accident has remained unreduced a certain time, the teeth of the two jaws partially approach one another, but not completely, on account of the mechanical opposition produced by the coronoid process being in contact with the malar bone. I have told you, indeed, what you would have known without my assistance, that great imperfection of speech is produced, and the patient finds it impossible to pronounce the labial consonants. At one time, it was supposed, that an unreduced dislocation of the lower jaw would be fatal: it is certainly a very distressing occurrence; but there is no truth in the statement that it is fatal; for, cases are on record of individuals who lived many years in this pitiable condition. When the jaw is dislocated, you will observe, in addition to the symptoms I have mentioned, a kind of depression in front of the meatus auditorius externus, in consequence of the removal of the condyle from its natural situation. When the dislocation is only on one side, of course, this depression will be perceptible on that side only.

Now, gentlemen, in the treatment of these dislocations, there are two indications to be attended to, which apply equally to all other dislocations, namely, *to reduce the displaced part or parts of the bone, and to keep them reduced.* The manner of reducing a common and complete dislocation of the lower jaw is very simple. The mouth is already open, so

that there is space enough between the teeth to admit of the introduction of the thumbs into the mouth, and the performance of the method of reduction, which I will in a moment describe. Well, the surgeon, recollecting the principle, which I explained to you in my general observations on dislocations, endeavours to make the dislocated bone a lever for reducing its head, or its condyle, as in this instance; he therefore introduces his thumbs into the mouth, and applies them on the molar teeth; in short, they are to serve as the fulcrum, on which he is to make the bone move: his fingers are next applied underneath the chin to the body of the bone; he now pushes the condyles with his thumbs downwards and backwards, at the same time that he brings the chin upwards and forwards with the pressure of his fingers; and, as soon as the condyles are thus extricated from the zygoma, the temporal and masseter muscles act so quickly and suddenly in pulling them back into the glenoid cavities of the temporal bones, that if the surgeon were not very prompt in moving his thumbs towards the cheeks, out of danger, they would be severely bitten. It is on this account, that some practitioners, who like not this kind of risk, usually put on a pair of thick gloves, before proceeding to reduce a dislocation of the lower jaw. Indeed, the rapidity with which the bone returns into the articular cavities, when the condyles are extricated from their confinement under the zygomatic processes, is really surprising. Then the *second indication*, or that of keeping the bone reduced, is accomplished by a very simple plan: you know, that there cannot be any displacement of the condyles, as long as the mouth remains closed; and hence, as soon as the reduction has been performed, it is usual to apply the four-tailed bandage, to keep the mouth in this very safe and desirable position. The two front tails of the bandage are brought to the back of the head, and the two posterior ones applied to the forehead. The bandage is worn for about ten days, and the patient is restricted to spoon diet, and directed to avoid conversation. If there be a great deal of swelling, you must employ bleeding and other antiphlogistic measures. It is found that, when only one condyle is displaced, if you press with your thumbs on the molar teeth of both sides of the jaw, you will sometimes not succeed in effecting the reduction; and I therefore recommend you not to forget, on such an occasion, Mr. Hey's advice, which is, to apply your thumb only on the side where the dislocation has taken place, and to let the lever-like movement be directed particularly to the displaced condyle, and not to the other.

With regard to the imperfect dislocation, or *subluxation of the lower jaw*, when the condyle is thrown out of the inter-articular cartilage, the jaw is rendered motionless, and the mouth cannot be entirely shut. It is an accident that does not call for the interference of the surgeon, for the condyle usually returns

into its place again in a few minutes, without assistance. When the reduction of a dislocated jaw is attended with extraordinary difficulty, you should have recourse to bleeding and other means of weakening the muscles.

A person who has once dislocated his jaw, will always be very liable to the accident again from slight causes; and sometimes merely laughing, or yawning, will bring it on.

Dislocations of the clavicle are less common than fractures. The clavicle may be dislocated at either extremity, at its sternal extremity, or at its junction with the acromion; but the dislocation of the sternal end of the clavicle is by far the more frequent, and for two reasons; first, because that end of the bone is naturally more moveable; and, secondly, because its ligaments are considerably weaker than those which tie the other extremity of the clavicle to the acromion. The accident is not uncommon in children and women, in whom the ligaments are weaker, and the articular cavity shallower, than in male adults.

Now, gentlemen, let us inquire, in what direction does the dislocation of the sternal end of the clavicle usually take place? It happens in most cases forward, the dislocation of the sternal extremity of the clavicle backwards being a very rare accident, so rare, that Sir Astley Cooper, with all his experience, has only met with one example of it, and that was not produced by external violence, but was the result of great deformity of the chest and spine, whereby such a change was made in the direction of the whole trunk, and of the clavicle in particular, that its sternal end was thrown backwards. One curious result of this case was, that the œsophagus was dangerously pressed upon by the dislocated end of the clavicle, which the surgeon was obliged to saw off to save the patient's life. The dislocation of the sternal end forwards is much more frequent, and may occur in two ways, either from a fall on the shoulder, or from the application of external violence, which, by pushing the acromion suddenly and considerably backwards, gives a disposition to the sternal end of the clavicle to start forwards in the same proportion. The nature of the case will be quite obvious, on account of the superficial and prominent situation of the bone. The accident is attended with laceration of the ligaments and part of the tendinous attachment of the sterno-mastoid muscle. The treatment consists in the application of a wedge-shaped cushion under the axilla, to make the humerus act as a lever in propelling the shoulder outwards; in the employment of a bandage and sling to confine the arm in a position in which the elbow and fore-arm are duly supported, and held rather backwards, while the shoulder is inclined a little forwards; and in putting a compress on the sternal end of the clavicle, and keeping it there with the bandage.

The *acromial end of the clavicle* can be dislocated only in one direction, which is up-

wards. It cannot be dislocated downwards, for the root of the coracoid process of the scapula, and the ligament extending from this process to the acromion, resist a dislocation downwards; but sometimes, by great violence, the scapula itself is driven downwards, and the acromial end of the clavicle projects upwards. Sir Astley Cooper, in his work on dislocations, gives us a drawing of such a case. Here the ligaments, tying the clavicle and acromion together, are torn, as well as some of the bands of ligaments connecting the clavicle with the coracoid process. The treatment also consists in throwing out the shoulder as much as possible by placing a wedge-shaped cushion below the axilla, and in using the figure of 8 bandage, with a soft pad in each axilla, to prevent its margins from being chafed. When by this means the shoulders are drawn back, the acromion returns into its place. The arm is of course to be kept up with a sling; by such treatment, the case will generally proceed favourably.

Dislocations of the humerus at the shoulder are so common, that it is calculated they are as frequent as all other dislocations put together; and when you consider various circumstances relating to the shoulder joint, you will see many reasons for the frequency of these accidents. First, you will observe, that the glenoid cavity is very shallow and small in proportion to the size of the head of the humerus, which, in the perpendicular direction, is twice as broad as the articular cavity, and in the transverse direction, not less than three times as wide. Then, gentlemen, you are to recollect, that this joint derives no material strength from ligaments, the capsular ligament being particularly weak and thin below, where there is nothing to resist dislocation, and thick above, where the acromion, coracoid process, and triangular ligament, form insurmountable obstacles to such an accident. Next, you are to remember, that the shoulder joint is capable of motion in every direction, and the muscles surrounding it and attached to the humerus are very numerous, the consequence of which disposition is, that the head of the bone must in many positions make considerable pressure against the capsule.

Dislocations of the humerus would, indeed, be more frequent than they are, if the scapula were more fixed; but as this bone is as moveable as the humerus itself, the glenoid cavity accompanies all the movements of the head of the latter bone, and thus forms a very accommodating support to it.

The head of the humerus is subject to *three complete dislocations*, and one of an *incomplete kind*. The most common of the three complete dislocations, takes place downwards into the axilla. The next most frequent one, is where the head of the humerus is thrown under the pectoralis major and pectoralis minor muscles, on the sternal side of the coracoid process, so as to lie below the middle

of the clavicle. As the pectoralis minor is attached to the coracoid process, the head of the bone must pass under that muscle in order to reach the situation which has been specified. This fact, I believe, is not demonstrated in any preparations in London, but then, I think, Sir Astley Cooper mentions a specimen, from the appearance of which, it was inferred that the head of the humerus had certainly passed under the pectoralis minor, as well as the pectoralis major. The third complete dislocation is backwards, on the dorsum of the scapula, under the spine of that bone; but this is a very rare accident, so rare, that Baron Boyer, in the whole course of his experience, never met with more than two examples of it, one of which was accidentally noticed in a dead subject. Sir Astley Cooper, also, during an experience of more than forty years, has only met with two instances of it; so that you may consider the case as exceedingly uncommon.

In the most frequent complete dislocation of the humerus, then, the head of the bone is thrown into the axilla, and presses against the inferior costa of the scapula, passing into that situation between the long portion of the triceps and the tendon of the subscapularis, which tendon is sometimes lacerated by it.

In the *incomplete* dislocation, the head of the humerus is thrown forwards, and the capsular ligament lacerated; but the bone does not entirely quit the capsule, it takes up its position on the external side of the coracoid process; while, as you know, in the complete dislocation forwards, it is lodged on the *inner* or *sternal* side of the coracoid process.

Now, gentlemen, what are the symptoms of a dislocation of the head of the humerus into the arm-pit? I may begin the answer to this question by telling you, that *three symptoms are common to all dislocations of the shoulder*; first, *loss of the rotundity of the shoulder*; secondly, *a hollow under the acromion*; thirdly, *the acromion will form, or seem to form, a greater projection than natural*. In addition to these symptoms, when the head of the humerus is lodged in the axilla, there will be a lengthening of the arm; if you look at the patient from behind, the elbow of the affected limb will plainly seem to be lower than the elbow of the other arm; the elbow will also be inclined a good way from the trunk, and you will find that the patient cannot put it close to his side. This latter circumstance is one of the first things about which I usually make inquiry, when called to a supposed dislocation of the shoulder; and if I find that the patient can put his arm close to his side, I then know that there cannot be a dislocation into the axilla. In such a dislocation, he is also unable to raise his arm to a level with the acromion. In consequence of the limb being lengthened, and the humerus carried downwards, the deltoid is necessarily flattened, and this, not merely on account of the bone quitting its place, but from the fibres

of the muscle being put on the stretch. It is, indeed, in consequence of this that the arm is held out from the side. The long portion of the triceps is also stretched, and one effect of this is, that the fore-arm is always found more or less extended, while the stretched condition of the head of the biceps accounts for the hand being thrown into the state of supination. If you raise the arm up from the side, you may feel the head of the humerus in the axilla, and this very distinctly. In addition to the above symptoms, the functions of the joint are suspended, and, instead of free motion of the arm, you will notice an extraordinary rigidity of it. The manner in which the accident commonly happens is this:—the patient falls while his arm is raised from his side, or, I should rather say, he endeavours to save himself from injury by holding out his arm; the arm comes to the ground in this position, and the resistance of the ground suddenly throws the lower portion of the humerus upwards, and propels its head downwards, which latter movement is at the moment also promoted by the spasmodic and violent action of the pectoralis major and latissimus dorsi muscles. Thus, supposing the arm to be raised from the side at the time of the fall, without too much inclination either backwards or forwards, the dislocation will be into the axilla.

The other kind of dislocation, which is tolerably frequent, is where the head of the humerus is thrown under the pectoral muscles, and can be felt on the inner side of the coracoid process. One symptom, I may therefore say, is that you can feel the head of the bone in its unnatural situation; another is, that the axis of the bone will be directed towards this point, that is, it will not extend towards the glenoid cavity, but towards the centre of the clavicle: this, gentlemen, is a circumstance to which I recommend you to pay attention. Then the elbow will be seen to incline more or less backward. The head of the humerus being more wedged in its new situation at the inner side of the coracoid process, than when it lies in the axilla, you will find that the limb is more rigid, and that there is less possibility of moving it than when the dislocation is downwards into the axilla. The limb is also shortened, whereas, in the luxation downwards, it is lengthened. In addition to these, there will of course be the three common symptoms, which I explained to you, namely, a hollow under the acromion, a considerable projection of that process, and a diminution of the rotundity of the shoulder.

The dislocation forwards, under the pectoral muscles and centre of the clavicle, takes place in the following manner: while the arm is inclined somewhat backwards, and separated from the side, the person falls with great force on his elbow, or lower end of the humerus, the head of which bone is consequently forced upwards and forwards. Probably the bone does not always pass immediately underneath the clavicle, but undergoes that secondary

species of displacement, to which, on a former occasion, I invited your attention: it is first thrown under the pectoral muscles, and then the action of the muscles draws it higher and higher, till it is brought close under the centre of the clavicle at the inner side of the coracoid process.

A dislocation backwards can only happen when the arm is inclined forwards, across the front of the chest, and it is difficult to imagine how any force can act so as to dislocate the bone, even when the arm is in this position; for any force, at all likely to be applied, would merely propel the arm against the chest, and this, no doubt, is the reason why the dislocation backwards is so uncommon. As the head of the bone is always very conspicuous below the spine of the scapula, the diagnosis is not liable to any mistake. In this case, the elbow may not be separated from the side, as it is in the more common dislocation into the axilla.

What is the mischief produced when the head of the humerus is dislocated downwards into the axilla? There is sometimes a laceration of the tendon of the subscapularis; the tendon of the long head of the biceps is also stated to be sometimes broken, or displaced; but as far as the dissections of Sir Astley Cooper and Boyer go, it appears, that neither of these circumstances occurs. One instance, however, is recorded by Mr. Hey in his *Practical Observations on Surgery*, where, in a compound dislocation of the shoulder, which is an extremely rare case, the head of the humerus protruded through the integuments, and the tendon of the biceps was really torn. Of course, the capsular ligament is lacerated, and there may be laceration of other tendons and muscles.

The ancients, in their treatment of dislocations of the shoulder, overlooked two great principles, which ought always to be attended to in the reduction; I mean the making of extension and counter-extension. Their most famous plans, namely, the ambo of Hippocrates, and the suspension of the patient by his axilla over a door, or ladder, all aimed at bringing back the head of the humerus by the most direct track, without any regard being paid to what obstacles might be in the way. The consequence was, that great mischief was often done, and sometimes the neck of the scapula was actually broken off. Gentlemen, it is quite obvious, that every good plan of reducing these dislocations must include, as essential parts of it, extension and counter-extension. Counter-extension is performed by fixing the chest and scapula, which is usually done by means of a sheet, a folded shawl, or tablecloth, that is held by an assistant, or fastened to a staple in the wall, or to a post, or the practitioner may himself keep back the acromial end of the scapula with his own hand, while the assistants make the requisite extension. The pressure of the counter-extending means, however, must be carefully kept off the situation of the glenoid

cavity itself, as it would prevent the return of the head of the bone into it, but it may act upon the chest and rest of the shoulder without inconvenience.

CLINICAL LECTURES

BY DR. MAC ADAM,

Delivered at the South Eastern General Dispensary, Dublin, Session 1832-33.

LECTURE V.

Pathology and Treatment of Gastrodynia—Duodenitis.

GENTLEMEN,—It is my purpose to direct your attention this evening to some morbid affections of the stomach, which are very prevalent among the poor of this city, and of which you will see numerous examples among the patients of this institution. Cases of this kind more frequently present themselves to the attending physician, as in the greater number of instances such affections do not prevent the patient from going out, unless when unusually severe. This circumstance affords a striking example of the utility of dispensary attendance in familiarising the medical student with certain classes of cases that he has scarcely any opportunity of meeting in the wards of an hospital. When I was a student in Edinburgh, I attended closely to the practice in the Royal Infirmary, and took notes of a large proportion of the cases which came under the care of the clinical professors. Yet I can scarcely recollect having seen there one instance of the lighter forms of stomach disease, such as gastrodynia, pyrosis, idiopathic vomiting, &c. &c. and I can hardly call to mind a single example of dyspepsia, unless a few that were symptomatic of organic disease. It is obvious, that I must have remained totally ignorant of a very important and frequent class of affections if I had depended solely on the practical information I derived from my hospital attendance. The fact is, such cases were considered too commonplace and trifling to be admitted into a clinical ward, nothing but severe and well-marked specimens of morbid affections would do there. Now I do not mean to dispute the propriety of making disease, in its gravest form, a subject of serious study, but what I wish to demonstrate is, that its lighter forms should be equally an object of attention, and that this is of the greatest importance, both in diagnosis and treatment. Its utility, with respect to diagnosis, is obvious from this consideration, that those affections, which are marked by the faintest outlines, and present the least prominent characters, must frequently be the most difficult to discriminate, and consequently demand the closest attention, in order to enable the student accurately to recognise them, and in treatment the art of graduating remedies, so as to be in proportion to the degree of severity of the case, can only

be acquired by a familiarity with the lighter as well as the more severe affections.

These remarks more peculiarly apply to the description of cases for which I have been prescribing for the last fortnight, when it has fallen to my lot to see those patients who attended at the institution for advice; during this period, some cases of affections of the stomach have presented themselves to my notice, several of which have assumed that form designated gastrodynia, of the varieties of which I shall give you a short outline before I enter into detail of individual cases.

This term simply means pain in the stomach. It is not, properly speaking, a disease, but only a symptom attending several diseases, which have their seat in this viscus, or sympathetically affect it. It has been often regarded as a mere symptom of dyspepsia, which it unquestionably frequently is, but this is not however always the case. I have seen many cases of gastrodynia, which scarcely presented any other symptom indicative of gastric derangement, and some forms of it seem totally unconnected with any fault in the digestive process. These reasons, in addition to its frequent occurrence, the degree of suffering which it causes, its occasional long duration; and the various organic lesions with which it may be connected, justly entitle it to a separate consideration.

Persons affected with gastrodynia frequently present more or less of the symptoms of indigestion; the gastric pain, however, is the most prominent symptom. The time of accession and the duration of the paroxysm are very uncertain; it may attack in the morning, afternoon, evening, or middle of the night, but the morning and night are perhaps the most common periods; it may continue from one to several hours. The pain is often aggravated by walking, and sometimes slightly mitigated by applying pressure with the hand, or reclining on the left side. It frequently, however, is aggravated by pressure. The character of the pain varies very much, it is sometimes of an excruciating aching kind, attended with great mental depression. Occasionally the sufferer complains of a gnawing sensation, and very often of a feeling as if the stomach was squeezed forcibly together; sometimes the stomach feels empty, but frequently the pain is accompanied with a feeling of distension, which is relieved by the eructation of flatus, or a bitter, saltish, or sour fluid is forced up into the mouth, and occasionally a quantity of clear water is ejected from the stomach with considerable straining, and the disease is then denominated pyrosis, which not unfrequently forms the termination of a fit of gastrodynia. When the paroxysm of pain ceases, the patient is often free from all indisposition, but in many cases some degree of epigastric tenderness on pressure continues during the intervals of pain. Headach seldom co-exists with the pain, but when the head does become affected there is generally an abatement of the

gastrodynia. The pain sometimes radiates from the epigastrium towards the thoracic parietes, and is often of an intermittent character. There is seldom much thirst; the appetite is variable, sometimes less, at other times greater than natural. This malady often continues for several years without the general health or appearance of the patient being much affected, this however is not always the case, excessive emaciation, vomiting, and other dyspeptic symptoms sometimes supervene; and I have known a case of extensive organic disease of the stomach preceded for a considerable time by gastrodynia. When these latter symptoms do not appear, the disease is comparatively harmless, with the exception of the severe suffering to which it gives rise.

Having given this general view of the symptoms of this affection, I shall now endeavour to discriminate the various forms which it assumes, and to point out the different morbid conditions of the stomach on which they may depend, a task of some difficulty. The researches of recent pathologists have thrown considerable light on this subject, which, until lately, was but little understood. We are much indebted to Dr. Barras of Paris, Dr. Johnson of London, Dr. Abercrombie of Edinburgh for light on the pathology of this affection. Comparing what they have communicated on the subject with the results of my own observations, I conceive myself justified in considering that the following species of this disease may be distinguished from each other, and that each requires a line of treatment, in many respects, peculiar to itself:—

1st. Gastrodynia may depend on morbid sensibility of the nerves of the stomach, totally unconnected with any inflammatory action, constituting, in fact, neuralgia of the stomach.

2nd. It may arise from an inflammatory state of the gastro-mucous membrane.

3rd. It may depend on one or more ulcers in the stomach, the result of previous inflammation.

4th. It may arise from acrimony of the juices of the stomach.

5th. It may be caused by duodenal inflammation, or morbid sensibility.

6th. It may be complicated with, or symptomatic of, hysterical affection; or arise from flatulent distension of the stomach.

7th. It may originate from spasm, or, as it has been denominated, cramp of the stomach.

Perhaps other forms may also exist, which it would be irrelevant to my present object to enumerate. We shall proceed to consider the characters which distinguish these different species.

Neuralgic gastrodynia has been often confounded with gastritis, and much injury to the patient has been the consequence of this mistake, as the treatment which would be useful in the former would be injurious in the latter affection. The pain in this species, though often very severe, is sometimes relieved rather than increased by pressure. It often observes

regular intermissions; the tongue is white; there is no thirst; the appetite is often greater than natural; the pain is not unfrequently relieved by taking food, and renews its attack two or three hours after eating; diarrhoea is rare, the bowels being more generally obstinately constipated; the urine is usually pale, rendered frequently, and in small quantities at a time. The affection is often protracted for a number of years without much or any effect on the general health. There is seldom any febrile movement in the system, this occurs, however, in a few instances. Dyspnoea, palpitation, wandering pains, especially in the arms, loins, and lower extremities, are occasionally present.

The inflammatory gastrodynia, on the contrary, presents several features quite of an opposite character. The pain is seldom so severe as in the former species, is often only felt on pressure, which always aggravates it. It is without distinct intermissions, and never entirely absent. The tongue is often thickly coated with red, tip and edges; the thirst is almost invariably urgent, with great desire for cold drinks; the appetite is usually bad, sometimes amounting to a disgust for food; the pain is always much increased immediately after eating; and when the disease has existed some time, diarrhoea often appears; the urine is high coloured, not unusually abundant or frequently voided, it runs a much shorter course, though sometimes it is protracted for a considerable time. It always is of long duration, produces a morbid influence on the process of micturition, inducing hectic, hardness and frequency of pulse, loss of flesh and strength, sallowness of the face, and ultimately, in some cases, a fatal termination.

When gastrodynia is caused by ulceration of the stomach, the distinguishing characters are often obscure; it may, however, be suspected when the pain attacks with considerable regularity after meals, and continues during the process of digestion, especially if the pain be distinctly referred to a particular spot, and if there be at that spot tenderness on pressure. An intense pyrosis frequently co-exists, together with the ejection of an acrid fluid in considerable quantities from the stomach. There is sometimes a raw and tender state of the tongue, with the formation of minute ulcers or crepitous crusts; the pain sometimes has remarkable remissions.

When gastrodynia depends on acrimony of the juices of the stomach, it is most apt to make its attacks when the stomach is empty, and is relieved by alkalies and absorbents. Under this head may be included that form of gastrodynia which Dr. Barlow, in his article on this subject in the *Cyclopædia of Medicine*, seems to think the most frequent form, and which he supposes to depend on a peculiar irritation of the stomach, causing a redundant and unhealthy secretion of mucus, and he conceives the pain to arise from the

contractile effort which the stomach makes to detach and expel the offending matter; this may probably be the case in some instances, but I cannot admit it to be generally so; and it appears to me that he carries his favourite view a little too far, when he applies it to explain almost every variety of this affection.

When gastrodynia originates from an affection of the duodenum it frequently commences about two hours after taking food, and continues for some time; there are also frequently pain and tenderness excited by pressure in the right hypochondrium.

When this affection is complicated with hysterical symptoms, or depends on flatus, it attacks in violent paroxysms at uncertain intervals, continues no very definite time, and is accompanied with a feeling of anxiety, distension, and restlessness, and occasionally with some of the symptoms characteristic of hysteria. In such cases it may sometimes assume a spasmodic or neuralgic character.

The most important variety of gastrodynia is that depending on cramp or spasm of the stomach. This is one of the most painful affections, while it lasts, that human nature is liable to; it attacks in a sudden paroxysm of acute pain, attended with a weak pulse, palpitation, and sometimes sudden death; it is accompanied with a feeling of rigid contraction, violent twisting or tearing in the epigastrium, followed by painful and interrupted respiration, difficult articulation, small, hurried, concentrated pulse, occasionally coldness of the extremities, rigid contractions of the recti and gastrocnemii muscles. There is a feeling of a hard circumscribed tumour, perceptible to the touch, in the epigastrium, occasioned by the inordinate contraction of the muscular coat of the stomach. The diaphragm participates in the spasm, and becomes rigidly contracted, producing the difficult respiration and articulation. Probably many instances of the sudden and unexpected deaths which sometimes occur are occasioned by this affection; life, indeed, is incompatible with any long duration of the spasm. Cramp in the stomach is often brought on by eating cold indigestible food; sometimes it subsides without attaining any great violence.

In describing the diagnostic characters of these different species of gastrodynia, I would beg to press on your attention, that they will not always be as simple and uncombined in their course as it may be convenient to represent them for the purpose of instruction; for instance, gastritis and gastralgia may, in some cases, co-exist, or the latter, long continued, may induce the former; or gastritis having subsided, a morbid irritability of the nerves of the stomach may remain, constituting a true neuralgia. Vitiated fluids in the stomach may produce gastritis, or cramp, or the latter affection may occasionally occur in any of the varieties of gastrodynia. It is of considerable practical use to retain these considerations in recollection, as we may sometimes be obliged

to pursue a different or opposite mode of treatment in the same case, according as these different morbid affections alternate or are combined.

I have thus entered somewhat into detail in describing the various forms of this affection, because I conceive it is of the utmost importance to form correct ideas on this subject, as the most injurious consequences have sometimes arisen from the too exclusive views of the disciples of Broussais, who, in their inordinate zeal for the doctrines of their master, have not unfrequently mistaken cases of pure neuralgic affection of the stomach for gastritis; and some patients have, it is not improbable, fallen victims to the improper treatment thus adopted in consequence of this erroneous theory of the disease.

I shall now proceed to relate a few cases illustrative of some of the forms of the affection we have just been considering, after which I shall make some observations on the treatment suitable to each.

Mary W., æt. 40, is subject to attacks of pain in the epigastrium, which generally come on at about eleven o'clock at night. The paroxysm commences suddenly and generally lasts about three hours; the pain is sharp and always accompanied with sickness in the stomach, and after it exists a few hours, vomiting of a greenish bitter fluid supervenes, preceded by a straining, during which a clear ropy fluid of a bitter taste is discharged, accompanied with shivering and feeling of coldness in the extremities. The epigastrium is sore on pressure a little below the point of the xiphoid cartilage, and the tendency extends some distance under the margin of the ribs on the right side. Has occasionally stings of pain in the right scapula, and a bitter fluid sometimes rises from her stomach to her mouth. She complains of a feeling of distension in her stomach after eating, with a bitter taste in her mouth in the morning; no thirst, febrile exacerbations, or headach; appetite bad; tongue a little whitish; pulse 90, full; bowels and catamenia regular; skin of a slightly yellowish tinge. Became subject to the attacks of epigastric pain about two years ago, at first every day, but now it only occurs once a month. Observes that potatoes or tea aggravates her complaint, but fresh meat or fish produces no inconvenience. She was directed to take—*Pil. hydr. gr. iv., extr. hyoscyam. gr. iii. in formâ pilularum, o. m., and two tablespoonfuls of the following mixture three times a-day:*

R. Infus. quassiae, ℥ viii., Potass. sulph. ℥ ss. Tinct. calumb. ℥ ss. M.

Diet—Cocoa and biscuit for breakfast;—broiled lean meat for dinner.

This case appears to me to be the result of duodenal irritation, probably connected with a derangement in the biliary secretion. The object I have in view is to restore a healthy action to the liver by the mercurial, while the *hyoscyamus* may be useful in allaying irrita-

tion. The bitter mixture is intended to restore tone to the stomach, while the saline ingredient will excite the peristaltic action of the intestines, and promote the excretion of the bile. I have reason to believe that the treatment has relieved the patient.

The next case, Sarah S. æt. 20, of a full habit, exhibited the following symptoms:—She complained of pain in the epigastrium of a dull aching character, worse immediately after dinner, and at night before going to bed; relieved by lying down. The pain also sometimes attacks her immediately after breakfast, and is occasionally accompanied by flatus of the stomach, producing a feeling of distension which is relieved by eructations. There is some epigastric tenderness on pressure; no vomiting, nausea, or bad taste in the mouth; bowels and catamenia regular; tongue a little coated, pulse, 78, natural; some slight pain in the left hypochondrium. Gastrodynia first came on about three months ago, preceded by a pain between the two shoulders, which next day shifted to the stomach. Has been in the habit of dining almost exclusively on fried meat. She was ordered a blister to the epigastrium, ten grains of the subnitrate of bismuth, with twenty of the compound powder of tragacanth, divided into three parts, one to be taken three times a day; cocoa with biscuit for breakfast, flummery or beef tea in the afternoon. A few days afterwards this patient reported that she had used the remedies, and adopted the diet prescribed; and that the epigastric pain had entirely disappeared; the flatus of the stomach had also ceased, the tongue was cleaner, and she found herself quite well, with the exception of a slight pain between the two shoulders; had some slight nausea and vomiting yesterday, in consequence of taking one of the powders immediately after some gruel. The powders and diet were directed to be continued; and I have reason to conclude she has remained for some time past free from attacks of gastric pain.

Probably in this case the pain was the consequence of irritation of the mucous membrane of the stomach, caused by the use of indigestible food, which if it had been continued might have induced gastritis. The substitution of a less stimulant and more easily digested diet, the counter-irritation of the blister, and the restoration of a healthy action to the stomach by the tonic powers of the bismuth, effected the decided improvement which was evidenced when she next attended, and which we have grounds to hope will be permanent.

The next case to which I shall direct your attention, is that of Catherine D., æt. 60. She complains of a pain in the epigastric region when she rises in the morning, which subsides after being a few hours out of bed, with some soreness on pressure in the pit of the stomach, and in both hypochondria, which continues all day. The epigastric soreness and pain are not increased after eating, unless she takes her food late at night, which always

aggravates the attack the following morning; considerable debility and loss of appetite; bowels much confined; pulse 78; small and weak; tongue a little whitish; occasional palpitation; finds herself relieved by aperient medicine.

Taken ill three weeks ago, after exposure to cold, with a pain in her chest, and cough, the pain about four days afterwards shifted to her stomach, after which she had attacks of vomiting, coming on once each day, at the same hour, for three days successively, the matter ejected being clear water, the attack being accompanied with cold perspiration and chilliness. Finds a small quantity of meat to agree with her, but potatoes aggravate her symptoms, and produce flatulency. Is in the habit of living principally on tea, and frequently does not take any food till after two o'clock p.m.

I directed her to use cocoa and biscuit in the morning and evening, to take a small quantity of broiled meat in the middle of the day, to apply a blister to the pit of the stomach, and to take three grains of the subnitrate of bismuth, and six grains of the compound powder of tragacanth three times a day, and ten grains of the compound rhubarb pill every second night.

This case I consider one of neuralgic gastrodynia, probably originating from insufficient and debilitating diet; it is not unlikely that it was preceded by some degree of gastritis; which the epigastric soreness on pressure might lead us to suspect still existed; but this symptom is not uncommon in pure nervous affections of the stomach. The history of the habits of the patient with respect to diet, the pain not being aggravated by the use of meat, the absence of pyrexia, thirst, or coated tongue, and the periodical vomiting, seem to render it probable that the neuralgia is the most prevalent affection. I hope at a future period to be able to report to you the effects of the treatment which I recommended.

I shall now make a few observations on the treatment of the different varieties of the affection which we have been considering.

In the treatment of neuralgic gastrodynia, our first object ought to be to allay the morbid sensibility of the gastric nerves, after which we should endeavour to restore tone to the stomach and general system, and maintain a healthy action of the abdominal secreting organs. Before attempting to fulfil the first indication, we should satisfy ourselves that the case is a pure neuralgic affection, uncomplicated with an inflammatory state of the gastric mucous membrane; we should recollect that atony and irritation may co-exist or alternate, and consequently require a treatment having a twofold object in view. If we find some of the symptoms of gastritis, such as permanent epigastric soreness on pressure, coated tongue, thirst, and pyrexia to be present, we should first leech the epigastrium, then apply a blister, and enjoin a strictly antiphlogistic diet, pre-

vius to adopting the treatment suitable to the neuralgic form. When this complication does not exist, or is removed by the above means, the paroxysm of pain is best relieved by the use of narcotics. Dr. Dawson recommends the tincture of opium in large doses, a hundred drops at once, in some cold water, it certainly affords decided though temporary relief, but except in extreme cases, I should not recommend such large doses in the first instance. The hydrocyanic acid has a powerful effect in such cases, and may be given in doses of from one to four or five minims in distilled water, almond emulsion, or infusion of cinchona. The tincture, or extract of hyoscyamus, has occasionally been found useful; and the tincture of hops, in combination with the aqua lauro-cerasi, I have known employed with advantage. The volatile alkali, in conjunction with magnesia and hyoscyamus in mint water, together with fomentations to the epigastrium, will sometimes cut short a paroxysm, but a permanent cure can, in general, only be expected by fulfilling the second indication—that of restoring tone to the stomach and general system. This is to be effected by tonic medicine and carefully regulated diet. We should begin with the light bitters, such as the infusion of calumba, after which we may exhibit the sulphate of quinine, or sulphate of iron; but there is one medicine which I have found eminently useful, not only in this form of gastrodynia, but in several other varieties of the disease—this is the subnitrate of bismuth, I have employed it in numerous cases with the very best effects. I generally begin with from three to five grains, with double the quantity of the compound powder of tragacanth, given three times a-day. It may also be combined with aloes, rhubarb, or magnesia, according to the peculiarities of individual cases. It appears to act as a tonic and antispasmodic; it does not produce any perceptible effect except the mitigation, and, in very many instances, the total removal of the pain, and an improvement in the appetite and general health. I have never found it to produce any unpleasant symptom whatever. It is said, however, when given in large doses, to act as a poison, by producing inflammation of the stomach. It has also been accused of causing cerebral congestion. These effects it is right to keep in view, but they need not deter us from its use, in the moderate doses that I have recommended. In addition to these means, the most careful regulation of diet is necessary. We should investigate closely the kind and quantity of food the patient has been in the habit of using, and forbid any article that appears objectionable. Tea, fried meat, potatoes, salt fish, spirits, or malt liquors, are to be interdicted. Light nourishing animal food, beginning with chicken broth, or beef tea, and ascending gradually to mutton or beef, may be used, broiled; but small quantities should be taken at a time, and an interval of five or six hours allowed to intervene

between each meal. As a substitute for tea, weak coffee, or cocoa and sea-biscuit will be found to agree. A small quantity of old wine mixed with water may be used at dinner. The patient should be warmly clad, and directed to remove to a healthy situation in the country, or try the effect of travelling.

I shall defer the consideration of the treatment of gastrodynia connected with gastric inflammation, or ulceration, until an opportunity occurs of presenting to your attention some cases illustrative of these affections. When gastrodynia depends on a redundancy of the mucous secretions, or acrimony of the juices of the stomach, aperient medicines will be useful, a few active purges of calomel, and extract of colocynth will cleanse the stomach and bowels; mild cordials may be given in the intervals to relieve flatulency and abate uneasy feelings; absorbents and alkalies, lime waters, and small doses of opium may be occasionally given with advantage.

When gastrodynia occurs in hysterical constitutions it is probably of a spasmodic character, and will be relieved by the medicines suitable to such affections; carminatives and antispasmodics may be employed, or relief may be obtained by exciting a brisk action of the bowels by means of a strong enema. External stimulants, such as sinapisms, or frictions with strong spirits, will occasionally give relief.

I have frequently seen gastrodynia co-exist with a distressing feeling of distension, and the eructation of an immense quantity of flatus from the stomach; in such cases I have frequently used, with advantage, a combination recommended by Dr. Abercrombie, consisting of the following ingredients:—*R.* Ferri sulph. gr. ii., pulv. aloes, gr. i., pulv. aromat. gr. v. *M.* Fiat pulv. ter in die sumend., occasionally exhibiting draughts of the powder and tincture of rhubarb, with magnesia in aromatic water; or I have given the subnitrate of bismuth in combination with rhubarb or aloes in many instances with the best effects. When gastrodynia depends on cramp of the stomach and diaphragm, it requires the immediate use of diffusible stimuli and narcotics; one drachm of ether, with from thirty to fifty drops of the tincture of opium, may be given immediately, or the volatile tincture of valerian, or other similar medicines may be used; warm fomentations, or sinapisms, to the epigastrium should be applied; when the powers of life are sinking, brandy or other strong stimuli may be given.

Pain in the epigastrium may depend on morbid sensibility of the nerves of the duodenum, which will require nearly the same treatment as neuralgia of the stomach, but it not unfrequently is caused by an inflammatory condition of the mucous membrane of this intestine, constituting the disease denominated duodenitis, or gastro-duodenitis, when the stomach participates in the affection. We have lately had a case of this kind among our dis-

pensary patients, to which I shall now direct your attention; the patient presented the following symptoms:—

James M. C., æt. 46, sanguineo-bilious temperament, spare habit, ruddy complexion, countenance and adnata of a slightly yellowish tinge, a dairyman by trade, and a good deal exposed by his avocation to cold and wet; though not a drunkard, yet in the habit of taking drams of whiskey very frequently, complains of a dull pain in the epigastrium, extending along the right hypochondrium, immediately under the margin of the ribs, to about midway between the scrobiculus cordis and spine. This pain, though constant, is much aggravated at times, especially in the evenings; epigastrium and right hypochondrium under the margins of the ribs sore on pressure; pain is increased by full inspiration or coughing; the cough is frequent, especially at night; expectoration copious, clear, and white; occasional nausea; tongue a little coated and moist; much thirst, but prefers warm drinks; retched a little yesterday; the day before vomited, after drinking some whey, a yellowish bitter fluid; pulse 72, soft, weak. Illness commenced about fourteen days ago with cough and oppression; a few days after was attacked with a sudden pain in the epigastrium and right hypochondrium, with anorexia, constant bitter taste, headach, and frequent attacks of retching; five days ago had a purging of yellow stools, which lasted two days, but at present his bowels are regular; abdominal pain was mitigated after the purging. The chest sounds well on percussion, except in the inferior part of the right side, where it is rather dull, and a very slight crepitous râle is audible; urine high coloured, passed with a sensation of heat; sleeps best on the right side. I directed twelve leeches to be applied on the epigastrium and hypochondrium, and the parts to be well fomented afterwards, and small doses of the blue pill and watery extract of opium occasionally. Two days afterwards I found him much better, the pain and soreness considerably relieved, but still existing in a slight degree. I ordered him four grains of blue pill every night, and a mixture of quinia and sulphate of soda, two tablespoonfuls of which were to be taken twice or three times a day. Some days afterwards I found him quite free from all pain and soreness, and able to resume his usual avocations.

This case I conceive to be one of mild gastro-duodenitis, for the following reasons:—The predisposing and exciting causes were such as were likely to produce this disease, namely, exposure to cold and dram drinking, the latter often practised when the stomach was empty, as the lower orders, who are whiskey drinkers, conceive that a glass in the morning is peculiarly salutary. The seat of the pain and soreness on pressure corresponded with the situation of the duodenum, the nausea and thirst indicated that the stomach partici-

pated, either directly or by sympathy, with the disordered duodenum. The bitter taste in the mouth and the bilious diarrhoea proved the liver to be sympathetically affected, probably its secretion, at times suspended or diminished, became at other times unusually active, which gave rise to the diarrhoea. The patient had also some pulmonary affection, which preceded the duodenitis, but it was inconsiderable. There was no pyrexia to any extent, so I did not think it necessary to employ a general bleeding. I found leeches quite sufficient to relieve the local symptoms, and I afterwards gave some pil. hydrarg. ad. ext. opii aquos. to allay irritation and maintain the biliary secretion. I found our patient so much better a few days after, that I did not think it necessary to repeat the leeching or inflict a blister upon him. We see that in this case there was no very great degree of jaundice, which so frequently attends duodenitis. A retrospect of the symptoms renders the reason of this sufficiently obvious. The biliary secretion and excretion were only temporarily suspended or diminished, just sufficiently so to give a slightly bilious tinge to the countenance. If diarrhoea had co-existed with obstructed excretion of bile, the dejections would necessarily have been whitish, or resembling pipeclay in appearance. On the whole, the patient presented a very fair specimen of a mild case of duodenitis, which yielded to a very simple treatment, but which probably would have been easily exasperated into a serious inflammation, if the affection was mistaken for a purely bilious one, and the patient had been treated with active purgatives and large doses of calomel.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

DELIVERED

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE V.

Diseases caused by the Generative Functions.

GENTLEMEN,—At our last meeting I described some of the morbid effects of the excessive action of the genital function on adults; and I shall now proceed to consider their influence upon children and youth. In the course of my observations, I shall give you the opinions of many modern writers on this subject, and content myself with observing, that all the ancient authors held the doctrines now received, though they deduced from them erroneous conclusions. Were I to quote the opinions of Hippocrates and

his eminent successors to the present century, I should occupy your time with little advantage, because I should finally conclude with the opinions of recent writers.

This is a subject that has engaged the attention of our profession from time immemorial, though now generally neglected, and consigned almost entirely to unprincipled empirics. I trust I shall adduce such evidence and reasoning as will convince you of the vast influence of excessive genital irritation in the production of numerous disorders and diseases. I shall endeavour to elucidate a fertile source of human infirmities, and one of the most frequent occurrence, to which national writers have, in my opinion, paid too little attention. If the knowledge I am about to communicate be properly applied, it must be conducive to the interests of science and humanity.

Every one acquainted with physiology will acknowledge the existence of a universal sympathy between all the organs of the body, and that the disorders of the function of one part may derange the whole economy. This principle being admitted, and it might be proved by an immense number of facts and incontrovertible inferences, it is easy to comprehend the reason that dentition, the ingestion of improper food into the stomach, and irritation in the bowels from whatever cause, may excite irritation or inflammation in the genital organs, as well as in all others in the body. We see this exemplified every day at our dispensaries, where mothers apply for advice, on account of discharges from the genital organs of female children. This disease is extremely common, may occur from the moment of birth to the age of puberty, and is totally independent of gonorrhoea, though parents and superficially informed medical practitioners entertain the opposite opinion. I have described it fully in my works on midwifery and medical jurisprudence; and you will find an excellent description of it in Sir Astley Cooper's lectures on surgery, in Professor Dewees' work on diseases of children, in Dr. Jewel's work on leucorrhoea, and in Dr. Darwall's treatise on diseases of children. In fact, the repeated observations of the most eminent of the profession in all countries has confirmed the validity of this conclusion. Those who are engaged in the practice of medicine, will acknowledge that of all the prolific causes of infantile diseases, the exhibition of improper food, and repletion or over feeding, are the most common. In the whole course of my own experience, I never met with one mother or nurse who did not err on this point. Hence the frequency of the diseases of the digestive system of infants and children. There is scarcely an infant, from the moment of its birth to the age of childhood, and from this period to puberty, who does not suffer from constant intestinal irritation, in a greater or less degree; and this generally extends to the genital organs. The consequence is, that we

very frequently observe young infants instinctively pass the hand towards these organs, as they do to the mouth when dentition commences. A habit of touching the genitals is contracted at the earliest age, is continued to the periods of childhood or puberty, and ultimately induces the baneful practice of masturbation or self-pollution. A vivid sensation is excited, the act is reiterated very frequently, and soon becomes a habit. This is continued to the age of puberty, when the secretion and accumulation of the spermatic fluid render it almost irresistible. The predominance of the nervous system in children predisposes to it. This disastrous habit is seldom contracted by healthful and vigorous subjects, whose muscular and digestive systems are well developed, as such persons take exercise, are active, and have little time for reflection, or the vagaries of the imagination. It is most common among the delicate, sedentary, and those who lead an inactive idle life, whose digestive organs are generally disordered. I have already stated the axiom, that violent irritation of any system or set of organs in the body, may derange or disorder the whole. In illustration of this, I may observe that the irritation caused by the urine, or a stone in the bladder, or worms in the rectum, extends to the genital organs, excites erection of the virile member, and discharges in the female. Irritation in the stomach and bowels may produce the same effect, because these and all the organs in the abdomen are supplied by the spinal system of nerves, and consequently have a strong sympathy with each other. In this way we explain the reason why children who suffer from disorder of the stomach and bowels are almost constantly touching the sexual organs. The late Professor Todd, of Dublin, observed, in a paper in the Dublin Hospital Reports, that elongation of the prepuce was often induced in adult dyspeptics by a habit of pulling this part. It is well known that dyspeptics are often prone to sexual intercourse. It is on record, that children at the age of five or six years have attempted copulation, and commenced the baneful practice of masturbation. There is a case recorded in the *Dict. des Sci. Méd.*, of a child, who practised masturbation from the fourth year, was discovered at the eighth, continued this evil habit, though the arms were tied, by moving the lower extremities, and died in the act at the twelfth year. Numerous examples of this description might be quoted from the medical periodicals of continental Europe. Many of the foreign writers consider, that the frequent opportunities which children have of observing the inferior animals during copulation, are exciting causes of genital irritation. Some medical writers contend, that parents whose venereal desires are generally too much excited during procreation, transmit a similar propensity to their offspring, as well as the hereditary peculiarities of mind and body.

This proposition being admitted, it is evident that the physical causes already enumerated may excite genital irritation, and instinctively lead to abusive practices for its removal. Bad example diffuses this deleterious habit; and it is on this account it is so general in public schools, or wherever children are congregated. It cannot be too strongly impressed upon parents, that children should sleep in separate beds, and be removed from those who are more advanced in life than themselves, especially from domestics. Parents, preceptors, and professors, who have the care of youth, should strenuously observe this precept.

It had not escaped the observation of the great Roman moralist, who painted with such appalling truth the vices of the full grown man, what a serious duty was imposed upon the preceptors of youth to check the first appearances of vicious habits. He forcibly observes:—

“Exigite, ut mores teneros ceu pollice ducat,
Ut si quis cerâ vultum facit: exigite ut sit
Et pater ipsius cœtus, ne turpia ludant,
Ne faciant vicibus: non est leve tot puerorum
Observare manus oculosque in fine trementes.”

Juvenal, Sat. viii.

Nothing can be more just than the remark, that preceptors should prevent their pupils from falling into vices, though it certainly is no very easy matter to watch the hands and trembling eyes of a great number of children.

The vicious habit under consideration is much more general from the period of boyhood and girlhood until the adult age. It is excessively practised at puberty, when the development of the sexual organs and their sensibility become very much augmented, and is often continued, especially in colleges and schools, until the adult age. Puberty is followed by an excessive, almost an electrical excitement, not only of the genitals, but of the whole organs, which, when too frequently repeated, is succeeded by loss of appetite, indigestion, and hence a want of supply of nutriment to augment the growth. It is highly injurious to the development of the whole body, retards and prevents the growth of all parts, especially of the sexual organs, causes impotence and sterility, induces the multitudinous disorders and diseases already mentioned, while it abridges life, brings on a premature old age, and frequently sudden death.

This injurious habit is termed masturbation, pollution, manustrupation, from *manus* the hand, and *strupo* I dishonour, masturbation, self-abuse, onanism, secret vice, solitary indulgence, and, when it produces a constant discharge of semen, seminal weakness. It is extremely injurious like all other excesses of venereal pleasure, and produces nervousness, hypochondriasis, or lowness of spirits, indigestion, flatulence, melancholy, palsy, mania, epilepsy, nymphomania, satyriasis, impotence,

sterility, leucorrhœa, or female weakness, hysteria, curvature of the spine, hip bones, &c., often a great propensity to suicide, in a word, disorders and diseases of the brain, senses, as vision, hearing, &c.; of the lungs, heart, abdominal and genital organs. We often observe young persons, at the age of puberty, exceedingly low spirited, dyspeptic, and complaining of a thousand and one transient symptoms in different parts of the body. Dugès and others consider masturbation a frequent cause of rickets in female children, and of the deformities of the spine and pelvic bones, or those which surround the internal organs of generation in the female. Professor Davis of the London University, cites a number of cases, in his learned system of Obstetric Medicine, now in course of publication, of nymphomania, some of which were induced by unnatural excitation. He also gives a case, in which repeated convulsions were produced by the same cause. My much respected friend, Mr. Mason of Newington Butts, mentioned to me one of the most violent cases I have ever found recorded.

I might illustrate this position by examples almost innumerable, but I shall content myself by observing, that the prolonged abstinence from sexual congress, when the desire is imperious, causes in man, when in a state of health, and while a sleep, a spontaneous and voluptuous emission of the semen, and the slightest irritation will produce it, so that when desire is urgent, and the natural resource is absent, he avails himself of mental or mechanical excitation for his relief. Animals, as elephants, monkeys, dogs, horses, &c. procure unnatural seminal effusions. But mechanical irritation produces the most vivid excitement in the genital organs, and hence its application is effected when the natural excitation cannot be obtained, before and even after reason is matured. It becomes almost irresistible at the age of puberty, and estranges from natural pleasure. Those who observe a rigid continence, or who make much mental or corporeal exertion, are much less excited by amorous impulse, than those who live luxuriously and indolently. The organs decay in the continent, the venereal propensity is diminished, and is finally extinguished, though sometimes it becomes indomitable. In general, individuals, who consider sexual intercourse, unless connubial, sinful, obviate its necessity by restraining the imagination, and refusing the assent of the will to immodest thoughts and objects. When such persons are naturally developed, and refrain from sexual intercourse, the secretion of the spermatic fluid goes on, the semen is accumulated in its receptacles, it is partly absorbed into the system, but at length, by increase in quantity, distends the tubes that contain it, and is effused during sleep without any consent of the will, or any mechanical irritation of the genital organs. This is an involuntary act, and consequently is in no degree a moral turpitude. It occurs at

longer or shorter intervals, according to constitution; sometimes at the lapse of ten, twenty, thirty, or forty days, and at a period much more remote. It is not injurious to health under such circumstances, but highly so, if reiterated two or three times during a night, or at short intervals, which is the case with those who practise masturbation to excess. The interval between nocturnal emissions enables every individual to form a correct opinion as to the frequency in which he should indulge in conjugal enjoyment.

Some persons have the generative system preternaturally developed, or predominant; and a few physiologists have concluded that such are of the genital or uterine temperament. As a general rule we may inculcate, that parents should be cautious in their conduct and discourses before children, and preserve them from the contamination of domestics, and the too intimate association with individuals older than themselves. The turpitude of such persons and of nurses, in initiating young children into bad habits, is most reprehensible. Children and youth of either sex should sleep alone, and those who superintend scholastic and collegiate establishments should invariably enforce this precaution. They should cautiously and sedulously watch over the conduct of those tender beings intrusted to their guardianship, and prevent all improper associations between them. Bad example in schools is often the fertile cause of the vicious habit of exciting genital organs. When youth contract it, they generally acquire a total disrelish for the society of the other sex. Their imagination is in a constant state of excitement, is further stimulated by the perusal of erotic and licentious works, and these are now unhappily in general circulation, more especially in all large cities. It is true, that the vendors of such productions are, by the laws, liable to prosecution; but it has happened of late, that juries, influenced by a fallacious notion of liberality, have defeated the laws by acquitting such individuals. Every man of a properly constituted mind must admit the immorality of works of this kind, but the heterogeneous intellect of the majority of those who sit as jurors, accounts for the difference of opinion. The representations in such works tend to debase man to the level of the brute beast, and must be denounced as irregular and unnatural by every lover of Christianity. Nevertheless, works of this kind are accessible to youth, and are secretly conveyed into public establishments, so often as this can be effected, wherever young persons are congregated.

The bad effects of coition and of masturbation have occupied the attention of physicians in all ages. It was, and is, the general opinion among the medical profession, that all diseases, both acute and chronic, may be induced or aggravated by venereal excesses. The shock given to the whole nervous system at the moment of the seminal emission, if frequently repeated, will debilitate every organ in the body,

and, in some rare cases, excite the brain so much as to derange the intellectual faculties, induce mania, epilepsy, convulsions, idiocy, and even death itself.

All persons feel languid after sexual intercourse, some are greatly debilitated and have an irresistible desire for sleep. The sexual organs also suffer, as their nerves are supplied by the spinal marrow, which is a continuation of the brain. The senses become impaired, and loss of vision or hearing may be induced. I have already mentioned, on a former occasion, a remarkable case of loss of sight, caused by paralysis of the optic nerve, and might have cited several from the works of Tissot, Boerhaave, Van Swieten, and others. In fact, derangements of every organ in the body may be produced by excessive venery, and numerous examples of all are recorded. In the *Dict. des Sciences Médicales*, article *Masturbation*, and in other works, to which I shall hereafter refer, there is a host of evidence on this point. Disorders of the head, chest, abdomen are often produced by excess of coition, or onanism. The excess of the latter prevents the development of the voice, when it is practised before or after the age of puberty. Every one knows that the voice becomes stronger and more manly at this age, unless prevented by the cause we are now considering. It is unnecessary to state, that the voice is dependent on respiration to a considerable degree. It is a fact, that those who indulge in the baneful practice of masturbation have the chest incompletely developed, the respiration hurried on slight exertion, the heart palpitating, and they soon become susceptible of cold, catarrh, bronchitis, which generally, in such subjects, terminate in consumption. The heart and great vessels suffer from the imperfect respiration; they become diseased, gradually fail to perform their function; an imperfect supply of blood is sent to the different organs of the body; these can no longer perform their functions or uses in a perfect manner; the general health suffers; every function is imperfect, and death prematurely destroys life. When we analyse the phenomena that take place at the moment of the ejaculation of the semen, we can readily comprehend the explication of all the disorders to which I have alluded. Many instances are to be found in the annals of medicine, proving that epilepsy, convulsions, coma, and death, have occurred during coition.

The too frequent irritation of the generative organs in children injures the organs themselves; they become flabby and relaxed, though sometimes preternaturally developed at first. It is an axiom, that excessive exertion of any organ will prevent its development, just as excessive labour will arrest the growth of the body.

It appears by the preceding statements that the nervous, circulatory, respiratory, digestive, muscular, and genital systems may be affected with acute or chronic diseases, excited by the pernicious cause already mentioned; and it

is important to state, that this most frequently induces the latter class of maladies.

The disorder of the nervous function occasions a considerable diminution, and sometimes total loss of memory. The unhappy sufferer abandons all agreeable study, or any pursuit that requires much attention. The muscular power necessarily follows the diminution of the nervous or moral. There is nothing more common than to observe, in crowded cities and towns, young persons who walk with the body stooped, the gait unsteady, and incapable of supporting the least fatigue, presenting to the eye the characteristics of old age conjoined with youth. The eyes are sunken and dull, the face is pale, the forehead wrinkled, and covered with a red eruption; the body emaciated, the bones projecting, and the imprint of corporeal and mental enfeeblement apparent. Such persons suffer from the deepest melancholy, have a disgust for all the pleasures of life, and they too often fall victims to suicide. In general they are hypochondriac, imagining several diseases, or dreading immediate death. At this period they generally suffer from gastric derangement, depraved appetite, flatulence, pains in the stomach and bowels, and sometimes chronic gastritis and gastro-enteritis, spasms in the legs, night-mare, disturbed sleep, or disorders in the lungs, or of whatever organs are pre-disposed to disease. They are now attracted by advertisements in the public prints, and become victims of empirics.

It is, however, in children and youth, whose organs are not fully developed, that the deplorable and terrible effects of onanism are greatest, because they repeat it much oftener than adults. The latter, however, are sometimes affected with marasmus, or wasting of the body, induced by this cause. When there is great emaciation some persons improperly term it *tubes dorsalis*. The ancient writers supposed that the semen proceeded from the spinal marrow, and therefore applied the term in question. A more correct knowledge of anatomy and physiology has enabled us to conclude that the semen is secreted by the testicles, and that these organs are connected with the spinal marrow by nerves. It is now universally admitted, that the wasting of the body, arising from excessive venery, is caused by the repeated shocks the nervous system, or brain and spinal marrow, its continuation, receive, which diminish their function, or the functions or actions of all organs in the body. The commotion of the muscular system during the emission of the semen, more especially after masturbation, clearly explains the cause of deformities of the spine, and not the erroneous idea of wasting of its medulla or marrow. In fact, the term *tubes dorsalis* is excluded from all modern nosologies; it is only employed by practitioners of the old school, or by empirics. It is worthy of remark, that the inhabitants of the north practise masturbation less than those of warm countries;

are therefore much stronger and more robust. Those of Asia, Africa, China, and the equatorial regions, are excited by the heat of the climate, and employ factitious as well as a natural means for the alleviation of genital irritation.

A question was agitated by ancient writers, and it is one of deep interest in a medical point of view, whether coition or masturbation was more injurious to health. Mr. Hunter, our illustrious fellow-countryman, was of opinion, that one was as bad as the other, when practised to excess; but he ultimately considered the latter more injurious. This must be evident, when we remember that the latter is succeeded by much stronger muscular action, sometimes amounting to painful spasms, which compel the individual to suspend his efforts for some time. His physical sensations are more vivid, in consequence of the great stretch of the imagination, which represents, with great vivacity, the fantastic objects of his shameful transports. A second cause which renders onanism more dangerous than excess of coition is, that it is much easier to reiterate the one than the other. When man gives way, with intemperance, to the natural pleasures of love, the fatigue of his companion restrains him. The one is obliged to have the compliance of a female, while every instant is opportune to the other. The imagination of the one excites his organs, or the organs excite the imagination, while the other obtains an easy remedy in the absence of the other sex. No cause restrains the one,—a thousand the other, who follows natural enjoyments. Lastly; the great sadness and melancholy which succeed masturbation produce great debility, prevent the organs of the body from regaining their natural power, while these depressing causes are easily dissipated, and the organs speedily renovated after nuptial enjoyment, influenced by conjugal love and unsophisticated pleasure. It therefore follows, that the effects of onanism are much more durable and dangerous than those that result from the propagation of the species according to nature's dictates.

I might quote a host of authorities on the baneful effects of genital irritation on young persons; but shall content myself with the following extracts:—

Dr. Parry speaks of immoderate and precocious coition in the following manner:—*"Inde apud mares oritur cultus præcox et effrenus, quo nihil mentem magis infirmat, nihil corporis vires frangit, nihil articularum, ventriculi, cordis, cerebri, morbis virum magis obnoxium reddit."* (Pathology, 1825.) *"Hæc vero nimis culta,"* says Professor Gregory; *"valde nocet præsertim junioribus, quorum animos pariter ac corpora multum degenerat."* (Conspectus de Med.) Every person's feelings must convince him of the languor, lassitude, and inertness which succeed the evacuation of the spermatic fluid. This was noticed by Aristotle, who said, *"Tristiam autem multum seminis emissionem censet, cur ex omnibus*

animantibus homo maxime omnium, postquam concubuit dissolvatur et languescat."

Frequent seminal emissions, whether by coition, masturbation, or pollution, greatly debilitate the mind, and enervate the body generally, and the reproductive organs in particular, and these are rendered incapable of performing their natural function. Physiologists hold that the semen must be retained for some time in its receptacles, so that its thinner parts may be absorbed, before it can be prolific. Masturbation is highly injurious to health, is contrary to morals, religion, and nature.

Without the affectation of introducing religion into a medical subject, in which, however, morality is deeply interested, it may be remarked, that there is no vice against which the anathema of the gospel is more distinctly and plainly pointed than against the abuses of that passion which was given for the propagation of the species. Every candid reader of the sacred volume must be struck at the clear insight into the infirmities of human nature, which are therein displayed. These vices are condemned in the sacred writings, Gen. xxxviii. 10; Deut. xxiii. 10, 11; Lev. xv. 16; John iii. 9; Prov. xxii. 11; Matt. vi. 1; Cor. vi. 15; Rom. i. 8. Onanism is contrary to human nature; because it is beastly, terrestrial and unworthy of man. It is generally commenced before puberty, and at this period becomes inveterate, unless removed by continence or the pleasure of love; and if continued, excites an invincible estrangement from natural pleasure. When young persons are addicted to this destructive habit, they become inactive, dejected, fond of solitude, the appetite is diminished, there is great depression of spirits, and a total disinclination to activity, playfulness, and vivacity. These symptoms are greatly increased by the constant and frequent repetition of their cause. The forehead is partially covered with crimson-coloured hard pimples, technically termed *acne*. Such persons have a great timidity and disrelish for society. The memory is impaired, and the power of comprehension considerably diminished; all the mental faculties are so much injured, that stupidity, idiocy, or lunacy have sometimes appeared. The senses of vision and hearing become imperfect; and blindness from amaurosis, and deafness frequently occur. I was once consulted by a young man who had amaurosis of both eyes, whose spirits were as depressed as possible, and who finally confessed that excessive masturbation had produced his disease. Those who give way to this horrible practice, endure a contemptible existence during the remainder of life. Their feeble limbs are incapable of sustaining any of the labours necessary to existence, their intellectual faculties are inadequate to the performance of any great mental exertion; if they engage in marriage, they are generally impotent or sterile; and if they possess the power of procreation, their infants will be

feeble, valetudinarians, and enjoy a more miserable existence than the contemptible authors of their sorrowful days. The moralist, the legislator, and physician, should duly consider this important subject, and endeavour to prevent the numerous disorders which are caused by the vicious habits under consideration.

An ancient writer well observed, "Venus sine concubitu nunquam natura aut sapientia dixit." Man cannot violate the laws of nature, or rather of her divine author, without rendering himself culpable to this great preserver of all things, to the social body, and to himself. The sacred inspirations of infinite wisdom are the guides to men, as well towards themselves, as to society at large. In these we find the imperious law for the conservation of ourselves, and consequently that suicide is a crime. Our natural attachments to life, to our own welfare and happiness, convince us; that we are bound to respect these towards every member of society. Nature has also implanted in the heart of every well constituted adult, a desire to be united to one of another sex, and to exert the generative faculty for the maintenance of the species; hence man is not permitted to infringe upon this natural and divine law, lest he contribute to the destruction of a greater or less portion of the human race. He is forbidden to commit embryocide, feticide, infanticide, as well as homicide. Neither can the reproductive fluids be turned from their natural destination, without great moral turpitude, as such depraved aberration would tend to the destruction of our species, and of society. Addicted to the shameful and unnatural habit of masturbation, man isolates himself from society, concentrates all his affections in himself, offers none of the sympathetic sentiments which are natural between the members of society, and which so powerfully contribute to the good of all. Masturbation is therefore unnatural, and unworthy of rational individuals; it leads to the certain destruction of health and life, and must be considered both as suicide and homicide. It was punished with instant death, as recorded in the sacred volume, in the case of Onan. There are other nameless vices of the generative function which are punished with death or long imprisonment in this and other countries.

But the practice of masturbation during infancy, childhood, and the age of puberty, is not so criminal as at manhood; because the immature age and imperfect development of the sexual organs prevent the emission of semen, and the want of reason and judgment offer an excuse. Moreover, it is the general opinion of physiologists that generation is imperfect before the adult age; and that if offspring be procreated, which cannot occur during childhood, they will be feeble, unlikely to arrive at manhood, and scarcely ever at senescence or old age. It is also to be collected, the conduct of parents before and at conception, during pregnancy and at lacta-

tion, predisposes to, if it does not actually excite infants to, masturbation. I have already stated that the constitution, the physical and moral dispositions, manners, diseases of infants, are, generally speaking, the natural effect of the particular condition of those from whom they received life. It therefore follows that parents, who are generally influenced by excessive impulse, and keep the sexual organs in a permanent state of excitation, must procreate infants predisposed to unnatural genital excitation, which we may consider the chief cause of masturbation. If this inference be allowed, it is evident that parents ought not to effect generation during excessive or unnatural excitation, as it will impress the new being with an increased sensibility, which will be permanent. Hence the excitement of the imagination by moral or physical means should be avoided. The mother's excitement is communicated to the foetus in her womb; and, consequently, excessive sexual indulgence is injurious to the pregnant woman, and to the infant she nourishes, and to the milk she supplies. It, therefore, follows, that pregnant women and those who suckle should avoid whatever excites the imagination; and hence, stimulating foods and drinks are injurious to their offspring. Amorous pleasure, erotic meditations, and the moral and physical results will unquestionably act on the foetus, and influence its sensibility. Sexual pleasure should therefore be avoided after conception, as it is useless to reproduction, and injurious to the mother and the new being. It is avoided by all animals except man. It is interdicted by moralists and physicians, as prejudicial to the parents and their offspring. But mankind in general condemn this opinion, and act contrary to it. The baneful effects of coition after conception in both sexes, and on the new being, cannot be questioned by any one who is conversant with the science of diseases, or, to speak technically, with pathology. Dr. Harris, the first English writer on diseases of children, after observing that the inferior animals refrain from copulation after conception, thus comments on the conduct of man:—

"At vero genus humanum, (cujus ratio intumescens plerumque dictat cristas in sublime erigere et præ se brutum omne semper aspernari) quovis hirco ferè salacius, indomitam suam libidinem adeo nescit gubernare, ut à primâ conceptione ad ipsum parturiendi momentum fœminam vix desinat importuniùs exagitare. Hinc viri torosi et vegeti prolem valetudinariam non raro progignunt. Hinc annosi senes, scilicet ab effrænatis amplexibus (benigno naturæ favore) jampridem emancipati, liberos rectiùs valentes effœto suo semine plus semel procreant quam juvenes utuncque strenui atque æstu venereo flagrantissimi solent."—*De Morbis acutis Infantum, Londini, 1668.*

There can be no doubt entertained upon the fact that excessive venery during pregnancy is highly injurious to the mother, and the

ender fruit of her womb, by debilitating both, and often inducing abortion or miscarriage; and, after the seventh month of pregnancy, premature labour. The other position of Harris is equally valid, that old men procreate much more vigorous infants than those in the prime of life, who abuse the rights of marriage. My distinguished correspondent, Professor Dewees, of Philadelphia, has happily observed, in discussing this subject—"it is better to be old in years than in constitution." On Diseases of Children.

At our next meeting, gentlemen, I shall conclude my observations on this subject, and proceed to consider the maternal influence on the fœtus or offspring in the womb, including the power of the imagination of the mother in causing marks and deformities.

DR. CARRICK OF BRISTOL ON MEDICAL REFORM.

THE following eloquent and powerful address was delivered at the late meeting of the Provincial Medical and Surgical Association; and it so fully accords with our own opinions, that we insert it with pleasure. Dr. Carrick is not an anarchist who would wish to annihilate the existing corporations; he wishes for wholesome reforms in them only, and so do we. After some preliminary remarks, he said:—

"Gentlemen,—I have, however, on several occasions been asked, what the object and drift of the society really is, as if doubtful of its utility, or distrustful of its motives. Some men object to join the association because it may be considered in opposition to the Royal College of Physicians, the Royal College of Surgeons, the Worshipful Company of Apothecaries, the Universities of Oxford and Cambridge, the Medico-Chirurgical Society, the London Press, or other various reasons equally cogent. To such objectors I have replied, we are in opposition to no man or body of men whatever. We associate for the legitimate object of our own gratification, our own instruction, and the advancement of medical science in its enlarged acceptation; and thereby, we trust, for the benefit ultimately of our fellow creatures. For myself I am free to avow, that to have an oppor-

tunity of meeting such a numerous and respectable assemblage of my medical brethren as I now see before me, many from remote parts and some from a distance of 150 miles, is to me an ample recompense, were nothing more to arise from it. From my first entrance into professional life, it has seemed to me to be a most desirable and important object, to cultivate the friendship and society of my fellow labourers; to bring them frequently together, and to render them familiar with one another; and I can truly declare, that the happiest hours I have ever spent have been in the company of medical men. But besides the mere social enjoyment of such friendly intercourse, there are numberless advantages which arise from medical men associating with each other, and living together on gentlemanly and friendly terms. This circumstance was not overlooked by your venerable president and your able secretary at the last annual meeting, and might therefore be passed now; but the tale is a good tale, and cannot be too often told. There was a time, gentlemen, and that not a great while beyond the scope of my remembrance, when medical men were wont almost universally to live in a state of open hostility to one another,—when it was the custom to run down each other's professional character on all occasions; as if they could only hope to raise their own reputation on the ruin of that of their neighbour; and the more unblushing and unscrupulous their efforts in that way were, the greater at times seemed to be their ill-deserved success; for unfortunately the world are but too much disposed to lend a willing ear to scandal; and are but little qualified to form a correct judgment of medical merit. Happily this semi-barbarous, ungentlemanly, unchristian spirit has in these more enlightened days in a great measure subsided, and has become so universally disreputable, that those who still retain it, are constrained at least to cover it with the veil of civility; and I trust, gentlemen, many of you will see the day

when even this veil will no longer be wanted; and when jealousy and hatred, that unseemly speck and blemish, shall have been washed from the fair face of our humane and charitable profession: and of this I am certain, that nothing can have a more decided influence in furthering this desirable object, than the frequent assembling of medical practitioners in associations like this. But numberless advantages besides these, great as they are, must naturally flow from the well-directed influence of this association. Besides the opportunity it affords of a ready and easy means of collecting, preserving, and presenting to the medical public many valuable cases, and histories, and essays of great interest, which would otherwise be lost to the world, I cannot but look forward with I trust a well grounded hope, that this society may in time prove eminently instrumental in improving the condition and structure of the medical profession; the just and proper organisation of which, although hitherto grossly neglected by the legislature, is vitally important to the best interests of the state, and of each individual person. It was well observed by the respected parent of this association, in his excellent address already alluded to, that 'the organisation of the profession as it obtains, is not what it ought to be; for the whole system of medical polity in this country is both defective and erroneous.—Opinions differ widely as to the evils and the remedies, but few are found to commend the existing state of things. This subject is closely connected with the advancement of science; for if the profession were constituted as it ought to be, and as reason and sound principles dictate, the harmony, that would be thus established among the several departments, could not fail to prove a direct means of their co-operating more cordially and efficiently in extending the science and improving the practice.'

"Although it would be improper now to enter at large on the vast and trackless field of medical reform, I

cannot forbear, with your permission, gentlemen, to take advantage of the present opportunity of calling your attention for a few moments to this very interesting subject, in the hope that some of you will, at no distant period, be pleased to favour the society and the public with your deliberate sentiments upon it; for it is only in this way that correct, and useful, and practical results can be arrived at, on a subject so complicated and environed with difficulties as this unfortunately is. And I will venture to say, that the man who shall be able to point out a plan whereby these difficulties may be overcome, and a rational, practicable, and efficient medical reform effected, will deserve for himself a monument *ære et auro perennius*. This inquiry seems particularly to recommend itself to your notice at the present moment, when efforts are making to call the attention of the legislature to the correction of certain imperfections in the Apothecaries' Act, upon the result of which, although this is but a very limited portion of the subject, a great deal of good or evil must necessarily ensue. *It is evident that the whole existing fabric of medical policy is faulty from beginning to end.* It does not work pleasantly or well—not so well at least as it ought to work. On considering this subject maturely, it will be a rational object of inquiry, whether the division of the profession, which law and custom have sanctioned, into three or four distinct branches, is conducive, in the greatest attainable degree, to the advancement of the science, the welfare of the profession, and the benefit of the public at large.

"On one hand it may be alleged that the subdivision of labour is favourable to improvement, and necessary to perfection. On the other, it may, with greater show of reason, be urged that, although this principle is sound when applied to the mechanical arts, it may not hold good in the totally dissimilar and infinitely more complicated affair of physic and surgery; while it is not to be denied,

that numberless advantages would result from the simultaneous practice of the medical and surgical departments. How often must every physician have had cause to regret the loss of precious time in sending for a surgeon to perform the simple but all important operation of blood-letting, out of delicacy to the surgical department? How often has he lost the opportunity of valuable post mortem examination, which might have been easily obtainable had it not been necessary to call in the assistance of second persons or strangers, in moments of affliction, when the sensibilities of relatives, and their aversion to such examinations, were most feelingly awake? Many other advantages, of no trivial moment, present themselves to the mind from the combination of both departments, which I need not here enumerate. But then, it will with reason be said, that a common system of practice must require a common system of instruction. There cannot exist a doubt that for the full attainment of knowledge in the medical department, it is necessary that the medical student should become as fully and minutely acquainted with the anatomical structure, as the student in surgery; while on the other hand, a comprehensive knowledge of those various branches of science which have usually been considered as the more peculiar province of the physician, is scarcely, if at all, less necessary to those who intend to make surgery their profession; for when he comes into actual practice, he will find that for once he is called upon to exercise the mechanical or operative part of his calling, it will be ten times necessary for him to draw upon his stock of medical knowledge. True, a man may pass in the world for a physician, with only a general and not very minute knowledge of anatomy; or may act as a surgeon without having paid much attention to medical instruction; but few will deny that each of them would have been better qualified in his respective department, had he bestowed on his

education an equal attention to both. But if medical and surgical students are to pursue the same course of study and instruction, where, it will be asked, would be the ground for distinction in name or station? To these I must reply, distinction in rank, without difference in education or acquirement, must be equally unnecessary and unjust. Would I then break down all distinction in the profession, and leave every thing to chance, or individual assumption? That is by no means necessary. There might exist distinctions still more distinct, and more securely limited, than those which at present exist; but obtained by a different process, and conferred in a different way. But I must not trespass further. I am well aware, gentlemen, that I am treading on delicate ground, and have opened a subject on which there are various and contradictory opinions held, by the most respectable and honourable individuals; the knowledge of which difference of opinion warns me to be diffident of my own and charitable to that of others, on a subject so complicated and uncertain. It may to some gentlemen appear somewhat singular that I should have noticed this subject at all, or expressed myself as I have done. Suffice it to say, that I have lived to witness most material alterations in the state and circumstances of the profession. Nothing in this world stands still. We live in an age of rapid motion; and it is absolutely necessary, will we, nill we, that we should follow the course of events. We can no more revert to the days of Linacre and Henry VIII., than we can make the river run back to its source. That the primitive institutions of these worthies were essentially useful in those early days, when science was struggling to emerge from the darkness and mummary with which it had been so long enveloped, is not to be denied; and we are deeply indebted for their nursing care. The institutions of the College of Physicians, and other royal and worshipful corporations, gave an upward move-

ment to the whole profession at the time; but it may reasonably be doubted, whether their subsequent influence has tended to its progressive advancement. In this respect *these* institutions are not singular. Many other corporate bodies were, in the outset, well adapted for the then existing state of society, although they have long since ceased to keep pace with the progress of general information. The monastic institutions, for instance, were at one time of unspeakable benefit to this and to all other unlettered and uncivilised countries. But although grateful, as we ought to be, for the benefits then conferred by them, who would now-a-days advocate their continuance, or bequeath his fortune to build a monastery? Besides those above alluded to, there are other corporate regulations, devised for periods of darkness and ignorance, but totally unsuitable for the present times, which stand awkwardly in the way of the improvement of professional polity, and the advancement of medical science. The existence of apprenticeships as a necessary part of surgical tuition, is the great stumbling-block in the way of that uniformity of education which is so absolutely necessary towards breaking down those distinctions which so fatally obstruct the harmony and impair the usefulness of the medical profession. Were these artificial and antiquated barriers removed, this by far the most useful, most important, and most difficult of all professions, would be found to glide on in its mild and beneficent course, like a placid and unruffled stream, instead of the noisy, and frothy, and uproarious torrent, which it now too frequently presents. I would fain hope, gentlemen, that a happier era is about to open upon us. We live in reforming days; but I am not a radical reformer—I would not rashly innovate for the mere love of change, neither would I decline reformation where palpable defects or abuses demonstrably exist. When, however, I consider the many obstacles which still stand in the

way of wholesome and rational medical reform, and the various opposing interests, individual and corporate, which must be conciliated or overcome, I despair of living to see the day. Many of you will, I doubt not, have that satisfaction, and enter into that promised land, of which I can at best have but a Pisgah prospect. For my own part I can scarcely be considered as interested in the result; my race is nearly run. Yet although I can neither derive any sensible benefit nor injury from what may happen, I cannot but feel warmly interested for the honour and advancement of that profession in which I have been actively engaged for more than half a century. In the meantime, gentlemen, it behoves us, as members of this society, to do our best to eschew and turn aside the evil of an imperfect and ill-digested system. Your influence, well and temperately directed, may not be small in accelerating the necessary improvements in education and practice, as well as in extending the limits of medical science, and in diffusing its benefits to society at large—the object which must always be uppermost in all our aspirations and exertions. By acting with unanimity and kindly feeling towards one another, and with uprightness, humanity, and manly independence to the world at large, we shall best succeed in procuring for ourselves that protection and encouragement for our useful services which the legislature is either too fully occupied otherwise, or too indifferent about the matter, to attend to; and which the corporate bodies are, perhaps, too much interested in withholding. Gentlemen, I beg to apologise for having engrossed so large a portion of your valuable time, and to thank you for your indulgent attention.”

THE
London Medical & Surgical Journal

Saturday, August 10, 1833.

THE POWER OF CONFERRING MEDICAL DEGREES IN LONDON.

WE were the first to propose, that the College of Physicians, when properly reformed, ought to possess the power of conferring medical degrees, because their examinations of candidates, which are certainly illegal and a direct insult to the Universities, are exactly similar to those of the latter institutions. One of our contemporaries, with his accustomed modesty, makes the same proposal as an original one, as if our numerous readers were likely to give him the slightest credit for the priority of a suggestion to which he has no claim whatever. We congratulate him upon his abandonment of medical toryism, and upon his joining us reformers; and he is really entitled to great credit for turning his back upon his former friends, when we reformers had rendered their condition hopeless.

With respect to the College granting degrees, we maintain our original position, that the whole profession, with the exception of those who live by collegiate abuses, would oppose it, until a radical reform takes place in the institution in question. There cannot be the slightest doubt, we rejoice to announce, but that such reform is inevitable; for the House of Commons has determined upon the measure.

It will be seen by the petition of the members of the College, in another page, that the abuses in it are now known to the legislature; and we know that the College will be compelled to give the most minute account of its proceedings, since 1771, on the meeting of the next parliament. We cannot help observing, that the privacy with which the physicians' petition was signed was unfair to the great majority of those in London, who received no intimation about it, except in the pages of this Journal. It might have been signed by three times the number of members of the College had proper notice been published in the newspapers that such a proceeding was determined upon. The petition, however, is very respectably signed, and has had great weight with the House of Commons. We beg to reiterate a former statement of ours, "that the state of the profession in the United Kingdom will be inquired into early in the next year, and a total reformation effected in it." We have now triumphed over the lukewarm friends of reform,—those who were afraid to advocate the measure a few months since, and who have now petitioned parliament for it. We look forward with pleasure to the labours of the Medical Reform Association, which will very speedily aid the glorious cause of science and humanity. Yes, we shall have reform as well as the law and church; reform is the order of the day! and medical monopolists are not the individuals to arrest its progress.

LONDON UNIVERSITY CHARTER.

THE subject of granting a royal charter to the University of London has occupied much the attention of the medical profession; nor is this to be a matter of marvel when it is remembered how many conflicting interests are put into the scale,—how severe a kick may be given to the balance of the private, metropolitan, and provincial lecturers by the doctissimi viri of the University, should the power and privilege of a royal charter be granted to them. A meeting of the metropolitan hospital lecturers was held a short time since, at which the sentiments and feelings of this small minority of the profession were discussed in a free, candid, and honourable manner. Yet, much as we admire the sentiments spoken on this occasion, we yet hope that a general meeting of the metropolitan lecturers will be summoned, at which the propriety of granting a charter to the University of London may be freely and ably discussed; it is one on which great difference of opinion exists,—one in which numerous powerful and conflicting interests are blended,—one which concerns the whole body of the profession at large. The meeting held at Dr. Hue's was composed of private hospital lecturers only, among whom we have heard that Dr. Chambers was proudly distinguished for the liberality and justice of his sentiments; but the voice of one man is not the voice of the profession; and therefore do we again urge upon our professional brethren, the neces-

sity of speedily calling a meeting of the hospital and general lecturers of the metropolis, to discuss calmly and deliberately so great, so important a question.

With respect to the power to be thus granted to the University, most assured are we that it is one requiring mature judgment, calmness, and decision in those wielding it. It will be an instrument for good to those who will be educated within the walls of this new alma mater, and to the nation at large. To them will the faculty of medicine be responsible—by them will they be judged if those bright prospects now opening to this institution do not raise it to that rank and station which its sister universities so proudly occupy.

PETITION AGAINST THE ROYAL COLLEGE OF PHYSICIANS IN LONDON.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled,

THE PETITION

OF THE

UNDERSIGNED PHYSICIANS, PRACTISING IN LONDON,

“**HUMBLY SHEWETH,**—That the charter of the Royal College of Physicians of London was granted by Henry the Eighth, for the advancement of Medical Science, and for the protection of the public ‘against the temerity of wicked men, and the practice of the ignorant.’

“That six physicians were named in the charter, who, together with all men of the same faculty, then resident in London, were constituted one body, commonalty, or perpetual college.

“That the perpetuity of the college was to be kept up by the future admission of all men of the same faculty into the college.

" That several of the six physicians named in the charter, studied at, and possessed degrees from, foreign universities; and that no distinction is mentioned, as regards the University where a physician may have obtained his degree.

" That all physicians entitled to practice in London, are equally entitled, under the charter, to admission to the fellowship of the college.

" Your petitioners are prepared to show, that by-laws have been framed, and long acted upon by the college, which are directly opposed to, and in violation of, the letter and meaning of the said charter.

" That the physicians practising in London, are invidiously divided, by the by-laws of the college, into two orders; one is denominated Fellows; the other, constituting by far the majority, is designated (and by implication degraded) by the term Licentiates.

" That the Fellows have usurped all the corporate power, office, privileges, and emoluments attached to the College; that the Licentiates do not participate in these benefits, but are illegally excluded from all the offices, and any share in the management of the corporation; and so far is this principle of exclusion carried, that the Licentiates are not even admitted to the library or museum of the College.

" That there exists no foundation in the charter, or in the acts confirming it, for such distinction of orders, and consequent exclusion from all privileges.

" That, according to one of the by-laws, no physician can claim admission as a Fellow, unless he has graduated, or been admitted *ad eundem* at the Universities of Oxford or Cambridge, where medicine is imperfectly taught, while physicians who have graduated at other British or foreign universities, celebrated as schools of medicine, are unjustly excluded from the fellowship by this obnoxious by-law.

" That the College was admonished

from the bench, by the Lord Chief Justice Mansfield, to amend their by-laws, in reference to the admission of Licentiates into the fellowship: that, influenced by this censure, the College framed other by-laws, deceptive in their character, which, whenever they have been acted upon, have tended still further to depress and injure the order of Licentiates.

" That the College demand and receive a large sum of money from the Fellows and Licentiates, for the supposed privilege of practising as physicians, within a circuit of seven miles round London, and that they do not and cannot protect them in this privilege.

" That the Graduates of Oxford and Cambridge are obliged to be members of the established church of England, and, consequently, all dissenters are excluded from claiming the fellowship: this, your petitioners consider as a grievous injustice, and an act of intolerance unbecoming the present age.

" That these invidious by-laws, made in the spirit of corporate monopoly, have involved the College in continued litigation, and created a jealousy between the Fellows and Licentiates discreditable to the members of a liberal profession.

" That your petitioners, with deference, submit, that the College of Physicians, as at present constituted, is wholly inadequate to the due regulation of the medical profession in this country, and the protection of the public; and further, that the charter of the College in no way provides for the practice of physicians in the several counties of England and Wales.

" Confiding in the wisdom of Parliament, your petitioners therefore pray

" That your Honourable House will institute such inquiry into the state of the medical profession in this country, and the College of Physicians in particular, as will lead to the framing of laws, by

which the evils complained of may be removed.

“And your petitioners will ever pray, &c.

PRACTICAL OBSERVATIONS ON CAN-
CER OF THE RECTUM.

CANCER of the rectum is generally distinguished by a sensation of pricking and heaviness in the part, accompanied with tenesmus and severe pain on passing an evacuation, especially if the bowels are in a costive state. On making an examination, a general, but sometimes only a partially, hypertrophied state of the sub-mucous cellular tissue of the inferior portion of the rectum is discovered. As the disease goes on, the pain augments, the intestine shrinks, and the fluid contents of the bowels only are evacuated, the more solid fæcal matter remaining behind. It sometimes happens that the coats give way, and the patient dies of the consequent inflammation;—this, however, is rare. More commonly, when the disease has been neglected, the scirrhus part softens, ulcerates, and passes into the state of carcinoma; the pain now becomes acutely lancinating; there is a fætid discharge from the anus, with hæmorrhage, colliquative diarrhœa, and hectic fever. A spiculum introduced into the rectum in this stage of the disease, only serves to irritate the parts and make them bleed.

This disease will sometimes arise without any evident cause. Constipation, the lodgment of hard feces in the rectum, first irritating and then ulcerating the mucous coat of the bowel, large hæmorrhoidal tumours, foreign bodies introduced into the rectum, suppressed discharges, old fissures of the anus, all these will be sufficient to lay the foundation for cancer of the rectum; it is, however, to syphilis that we must look for the chief cause of this affection in females; it may also occur in them from the natural cessation of the menstrual discharge. It is only in the early stage of this disease that medical treatment will at all avail. If it proceeds from syphilis, mercurial sudorifics may be given, and mercurial suppositories introduced into

the rectum, combined with opium or extract of belladonna if the pain be very great; when it arises from a suppressed discharge, it ought to be brought back; if the heat and irritation be very great, leeches may be applied. Whatever treatment, however, be adopted, it will be necessary that the patient have oily or mucilaginous injections administered to soften the hard faecal matter, and allow of their more ready expulsion. When the intestine retracts, some method of compression should be kept up by a dilating substance, such as a tent, or canula, or bougie introduced into the intestine; the best remedy of this kind that can be employed, consists of a fold of linen, gradually increased in size, and covered with some medicated ointment, in order to modify the affection, or to resolve it altogether, if possible. There is but one remedy which will securely rid the patient of the complaint, and that is, the excision of the scirrhus portion of the intestine. M. Lisfranc's method of performing the operation is this:—at about an inch from the external orifice of the rectum two semilunar incisions are made, meeting above and below, including the skin and subjacent cellular tissue. The surgeon then, introducing his finger into the rectum, draws it down and excises it with a strong pair of scissors above the reach of the disease. M. Lisfranc only performs this operation upon cases of superficial cancer. When, however, the disease has affected the entire coats and circumference of the intestine, the operator having proceeded as above, and drawn down the intestine, a third incision is made parallel to the axis of the intestine, beyond the extent of the scirrhus. This last excision is made on the posterior side of the rectum, because there is then less risk of wounding the vagina in females, or the urethra in males; and that fewer large blood vessels are likely to be injured, and that the whole extent of the disease may be extirpated.

PROTIODIDE AND DEUTIODIDE OF MERCURY.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN—As the following extract from a lecture at the Westminster Dispensary may be useful in showing the decided difference in medicinal activity between the *protiodide* and the *deutiodide* of mercury, and also the necessity of stating in a prescription the one that is to be employed, I beg your insertion of the same. I might add an additional reason, namely, the discredit that might otherwise, from inattention to the distinction, be brought upon so valuable a medicine as *iodine*.

Believe me, yours, in well wishing,
JOHN EPPS.

89, Great Russell-street,
August 5th.

“I have now, gentlemen, to draw your attention to a new preparation of mercury;—it is the *iodide*. This preparation has been employed in the removal of tumours, and with considerable effect. I have tried it both internally and externally. From my own experience, I have more confidence in its *external* application than in its *internal* use. I have used it with success in scrotal tumours, but in some instances I have been disappointed. These disappointments I am inclined to ascribe (from one circumstance that has lately occurred) more to the *preparation* of the medicine than to the medicinal agent itself.

“In illustration, I shall mention a case. A patient, who had been taking the tincture of iodine without any effect for a scrotal tumour, applied to me in the month of February last. I prescribed the following:—*R. Iodid. hydrargyri, ʒj., Ung. cetacei, ʒj., ft. ung. pro usu.* At the next visit from my patient I found that no effect was produced upon the tumour; in fact, no effect at all, either general or local. This I thought strange, because I knew that the iodide of mercury produces generally great heat and irri-

tation. I then ordered an increase of the iodide to two drachms; still the patient complained of no effect being produced. I then ordered him to go to some other chemist: he went to Mr. Bell, in Oxford-street; and returned to me in astonishment and anxiety two days after, stating that the ointment which he obtained there from the presentation of the same prescription was a beautiful *bright red* colour, whereas the one that he obtained at the other chemist's, in Oxford-street, was of a *yellowish-green*. And not only did he notice the difference in colour, but the difference in effect; for after applying the red ointment, on going to bed, to the scrotal tumour, it produced so much irritation that he was obliged to rise in the night and bathe the part.

"In order that I might be fully satisfied, I desired him to take the same prescription to the two chemists, and have the ointment made up at both, and to bring me the same, which, gentlemen I now show you; and one you see is a *yellowish-green*, the other a *light red*.

"Now, gentlemen, I am willing to allow that I am in part to blame, as the following explanation will prove. There are *two* iodides of mercury, the *protiodide* and the *deutiodide*; the former composed of *one* equivalent of iodine and *one* of mercury; the latter of *two* of iodine and *one* of mercury. The former is of a yellowish-green colour, the other of a bright red. I should have written in my prescription the deutiodide; but, notwithstanding, you will perceive that the one chemist introduced the protiodide, the other the deutiodide, in making up the *same* prescription.

"Thus, gentlemen, you will perceive that it is our duty to avoid even the possibility of a mistake; and I trust you will remember this additional illustration of the great difference in the properties of a medicine connected with the addition of an atom.

"As an additional proof of the greater activity of the deutiodide, I

may remark, that the use of the deutiodide *softened the tumour*; and in addition to the irritation produced by its application to the part, the patient noticed another and an interesting fact, namely, that he *tasted* it the day after rubbing it on the scrotum.

MALIGNANT CHOLERA—LARGE DOSES OF MERCURY—DEATH.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I send you some account of the case you saw with me on Saturday evening last, which I regret to state has terminated fatally. It is as follows:—

Mr. —, ætat. 30, and much addicted to drinking, had been affected for some days with pain, uneasiness, and relaxation of the bowels. On Saturday morning the pain in his bowels was much increased in severity, and the diarrhoea and vomiting were violent and distressing. He complained of cramps in his legs, and there was a general coldness of the surface of the body. He had taken the day previous to his attack nearly a gallon of ale and seven strong glasses of gin and water. I was called to him about eight A.M. The pulse at the wrist scarcely perceptible, with all the above mentioned symptoms. Hot brandy and water administered, and continued frictions of the body by the female attendants. Hot bottles of water were applied to the feet and hands; a mixture of mist. cretæ. tinct. opii, tinct. kino, conf. arom., &c., was ordered. Two P.M., the vomiting, purging, and cramps had ceased entirely, but the articular coldness still remained. Frictions continued; warm gruel, impregnated with brandy, administered. About eight P.M., you saw him, there was then apparent reaction. Hydr. submur. ℥j every hour, and ung. hydr. fort. ʒj to be rubbed into the axillæ every quarter of an hour, and the astringent mixture, if necessary, were ordered. I saw him again about twelve P.M., he appeared much better;

the surface of the body was warm, and the pulse perceptible. He expressed his certainty of recovery, and joked his attendants. About a quarter of an hour after I left him, he was suddenly seized with a violent inclination to vomit (his stomach had been hitherto tranquil). He suddenly sprang up in the bed, made one or two powerful attempts to vomit, and immediately fell back and expired without a struggle. No ptyalism had been produced; and no post-mortem examination was allowed. It is to be regretted that the hidden cause of death was not permitted to be revealed by dissection, for I think it is clear that he could not strictly be said to die of cholera. I cannot but think that the fatal termination of this case was owing to the rupture of some important vessel. My time will not allow me to enter at length upon this subject, but I think some remarks upon it, and upon the most probable cause of death, from your able pen, could not fail to be interesting to the numerous readers of your valuable journal.

I am, Gentlemen,
Yours, with much esteem and respect,
EDWARD AUGUSTUS CORY.

[It would be a difficult matter to account for death in the above case as there was no autopsy allowed; cholera seldom terminates so suddenly.—Eds.]

SIMPLE PROCESS FOR MAKING PRUSSIC ACID.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Will you allow me to submit to the readers of the London Medical and Surgical Journal a new formula for the extemporaneous production of medicinal prussic acid. By its adoption this very powerful medicine may always, in a very few minutes, be made of a known and uniform strength, and of a quality (owing to its freedom from mineral acids, and

the presence of alcohol) that effectually preserves it from spontaneous decomposition, advantages which, I need hardly observe, are unattainable by any other known means. The quantity of cyanuret of potassium, apportioned in the formula, to a fluid ounce of the solution, is the exact equivalent for supplying eight grains of absolute prussic acid, and the extreme facility with which that salt is decomposed by tartaric acid, ensures that the whole of the prescribed strength shall be obtained; the terms of the division of a fluid drachm of the medicinal solution will therefore be accurately expressive of the division of a grain of the strong anhydrous acid.

I inclose for your inspection portions, both of the medicinal prussic acid, made in this way, and of the cyanuret of potassium used in its formation; the latter of which I believe to be the first specimen of the salts ever obtained in a state of purity. With a view to its introduction into the forthcoming joint Pharmacopœia of the two Colleges of London and Edinburgh, I have been requested by the London Pharmacopœia Committee to furnish them with the plan for making it, and having done so, I must of course leave the question of its publication for the present in their hands.

I am, gentlemen,
Your obedient servant,
RICHARD LAMING, Surgeon.

48, Finsbury-square,
Aug. 5th, 1833.

FORMULA.

Take of

Cyanuret of potassium	22 grains
Tartaric acid crystals	50 grains
Distilled water	6 fluid drachms
Rectified spirit	3 fluid drachms.

In a phial, capable of containing eleven or twelve fluid drachms, dissolve the tartaric acid in the water and spirit, previously mixed together and suffered to become quite cold; then add the cyanuret of potassium, and immediately close the phial with a sound cork. After occasional agi-

tation during ten minutes, secure the cork, and set the phial aside for the supertartrate of potass to precipitate, when the clear solution may be decanted for use.

INGESTION OF BILE IN CHOLERA.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I beg to submit to your notice a question for consideration, relative to a proposed remedy for the treatment of cholera, viz :—

“Whether the introduction of bile into the intestines, obtained either from a carnivorous or herbivorous animal, might not be attended with some beneficial effect in arresting the progress of the diarrhoea?”

We have heard of saline injections being attended with benefit; and it is unnecessary for me to mention, that the bile contains within itself many saline and other properties, peculiarly and eminently adapted for the right performance of its very important functions.

I am, gentlemen,
Your obedient servant,
P. HOOD.

Norton-street.

MALIGNANT CHOLERA.

MR. JENKINS of Prescott-street informs us, that he has succeeded in curing twenty-five cases of blue cholera with pills, each containing $\frac{1}{2}$ of a grain of strychnia and two grains of confection of roses; one given every quarter of an hour, and, after some time, every half hour or hour. He has given three grains in thirty-six hours.

OPEN FORAMEN OVALE WITHOUT CYANOSIS.

IN a child of seven years, who never had any symptoms of the blue disease, the inter-auricular septum presented, at the site of the foramen ovale, a network of fibres, between whose meshes the blood might freely pass.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

A STRONG, robust, and healthy-looking man, æt. 50, was admitted Aug. 3, under Mr. Earle's care. He complained of a partial loss of vision in the right eye, occasioned by a blow which he received last Christmas. The crystalline lens is ruptured, and the retina, when seen at a distance of four or five feet, distinctly exhibits several delicate red lines, and a beautiful purple blush. The lines are evidently the ramifications of the arteria retinæ centralis. It is rather a curious circumstance that neither these lines nor the blush just mentioned can be seen when the eye is closely examined, but can be very clearly distinguished at a distance of four or five feet. The lines are observed with more precision by the light of a candle. The eye, at first view, appears somewhat amaurotic, being of a dull blackish colour.

We shall report the treatment and its results in the above case in our next.

ST. GEORGE'S HOSPITAL.

THE case of William Bowker, which we gave in last week's report (Compression of the Brain), is going on well; the febrile symptoms which remarkably characterised the commencement of the case have almost entirely disappeared. Pulse on Wednesday, August 7th, was about 70.

The alvine evacuations have been very regular. He seems cheerful, and recovery appears certain.

Fracture of the Clavicle, and Compression of the Brain.

Martha Toogood was admitted into the hospital on Monday, August 5, under the care of Mr. Babington, having received a very severe fall from a height of several feet. On her admission she was insensible, pulse feeble, pupil somewhat dilated,

respiration hurried. On examination we found that the right clavicle was fractured. There was also fracture of the occipital bone.

The patient has suffered considerable pain, and seems very restless. She complains of a lancinating pain in her forehead. To remove these pains anodynes have been administered; purgatives have also been given, but her evacuations by stool have been very irregular.

On Wednesday ten ounces of blood were taken from her arm.

EXTRAORDINARY FECUNDITY.

In the 88th No. of the "Severnaga Ptchela," a Russian periodical, Dr. Bajalskry relates almost incredible instances of human fecundity, among which the following are the most remarkable. In 1755, Jacob Kirilo, a Russian, had by one wife fifty-seven living children, viz. four quadruplets, seven triplets, and ten twins; by a second wife, one triplet and six twins. Fedor Wasiliewitz, of Schja, in Wladimir, had by his first wife, in twenty-seven accouchments, four quadruplets, seven triplets, and sixteen twins; by a second wife he had two triplets and six twins. Official documents show, that on Feb. 27, 1782, this Wasiliewitz, aged seventy-five years, had eighty-three children living out of eighty-seven born.

French Medicine.

Belladonna in strangulated hernia.

A MAN, aged 50, of nervous temperament, felt for some days severe passing pains over the lower part of the abdomen, and, after some slight effort, a large tumour appeared in the left groin. On examination, it was discovered to be an inguinal hernia. The tumour was hard, sensible to pressure, and occupied the whole of the scrotum. The efforts at reduction were unsuccessful, and the belladonna was tried. Equal parts of lard and belladonna were rubbed, every quarter of an hour,

over the abdominal ring and the neighbouring surfaces. In the space of two hours the tumour was much softer, and greatly diminished in volume; and the hernia was afterwards reduced without any difficulty. The abdominal ring remained open for some time after the reduction of the intestine, sufficient to allow of the introduction of two fingers. Notwithstanding a severe attack of constipation of the bowels the patient perfectly recovered.

A young girl, aged 13, after some exertion felt something glide along the inside of the groin; she went to her room and found a swelling in the groin, which, though discoloured, gave her no pain; she pressed the tumour, which immediately disappeared with a gurgling noise. The same accident was repeated several times, and the same means were always sufficient to reduce it, until the tumour descended, and became fixed so firmly, that it resisted all the usual means to restrain it. A nurse was called in, who declared it to be an enlarged inguinal gland; the pain greatly increased, and was succeeded by headache, thirst, constipation, and vomiting. A surgeon was now called in, who soon discovered that the enlarged inguinal gland was a crural hernia. The tumour was hard to the touch; the skin red, hot, and very sensible to pressure; the vomiting continued; the thirst was increased; the pulse sharp and frequent. Ten leeches were applied to the neck of the tumour, emollient and anodyne cataplasms to the part, and a lavement.

On the following morning the patient was in the same state, and it was impossible to reduce the hernia; ordered to be put into the warm bath, and afterwards the extract of belladonna to be rubbed freely over the crural arch. In the evening the hernial tumour was much diminished in hardness and size, and had ascended a little upwards towards the crural arch; pain greatly decreased. The taxis was now carefully used,

and in half an hour the hernia was reduced. In this case, as in the former one, the crural arch remained dilated for some time after the ascent of the tumour.—*Jour. Méd. et Chir.*

Chorea supervening upon apoplexy.

Steffany, a member of the National Guard, having partaken too freely of wine, was seized with apoplexy and hemiplegia; he was bled freely at repeated intervals with great benefit. Eleven days after the attack the parotid gland of the affected side (the right) inflamed, which spread to the cheeks and tongue, which latter was obliged to be lanced repeatedly to prevent suffocation. Four days after this inflammation, slight convulsive movements of the arm of the affected side were first perceived, and the muscles of the face and neck became similarly affected, until in a short time chorea was fully established, which lasted until the inflammation of the tongue and parotid gland had subsided, when it left the patient free from any complaint.—*Gaz. Méd.*

Pustular eruption.

A boy, aged 14, was suffering from irritation of the chest, for which he was ordered to rub in some antimonial ointment, $\mathfrak{z}\text{j}$. of lard to $\mathfrak{z}\text{j}$. of antimony; on the third day there was no eruption on his chest, but on the upper and inner part of the thighs a distinct well formed pustular eruption appeared, similar in all respects to that produced by the absorption of tartar emetic.—*Ibid.*

Narcotism produced by twelve drops of liquid Laudanum.

A man was admitted into La Charité for contraction of the rectum. The actual cautery was applied by M. Rayer a few days after his admission, and an anodyne lavement, containing 12 drops of Sydenham's liquid laudanum, was administered in the evening. Three hours afterwards he went to bed, and immediately was heard to groan several times deeply,

and grew very drowsy. At two A.M. he could not answer any questions; he gradually lost his senses, and soon fell into a deep coma, from which, however, he seemed to rally occasionally. In the morning he was found in a state of extreme prostration and collapse; profuse diaphoresis; eyelids closed; pupils contracted; respiration slow; pulse 110, and full; skin damp; urine increased in quantity, and passed for the most part involuntarily. Two porringers full of blood were immediately taken from his arm; the pulse rose to 150; and some vinegar and water were thrown into the stomach. Sinapisms were applied to his feet, but in the course of a few hours he died.

Autopsy.—The superior cerebral veins were gorged with black blood; the brain was not softened, nor was there any effusion of serum in the lateral ventricles. The superior longitudinal sinus contained nothing unnatural; the lateral sinuses were gorged with blood; the spinal marrow was natural; the rectum was found in a cancerous state for two or three inches; the intestines were more or less injected with blood; the mucous coat of the stomach was covered with reddish brown spots, and on the summit of the right kidney was a cyst, containing serous matter; the upper surface of the liver was marked by several tubercles of the size of filberts; the lungs were loaded with blood.—*Lanc. Fran.*

Case of poisoning by Digitalis.

A man was ordered to be rubbed with the tinct. digitalis for dropsy: mistaking the directions, he swallowed $\mathfrak{z}\text{ss}$. of it in three spoonfuls. Soon after taking the third dose he became nauseated, severe burning pain in the epigastrium, vomiting, colicky pains in the precordial region, contraction and convulsive irritation of the limbs. Severe headach and dyspnoea now came on, and the eyes became fixed, and seemed starting from their orbits. These violent symptoms lasted six hours. On the following morning the

pulse was not altered in frequency, the tongue was yellow and covered with a thick fur, and each side of the body was of a vivid red colour; all the other violent symptoms had gone off, and he appeared recovering.—*Ibid.*

**ENORMOUS DEVELOPMENT OF THE
SPLEEN AFTER INTERMITTENT
FEVER.**

Mary —, when 17 years of age, had a tertian ague, which spontaneously disappeared at the end of the month, leaving only some swelling under the ribs on the left side. After a lapse of eight years her abdomen had become as large as that of a woman in the eighth or ninth month of gestation. She then married, shortly after became pregnant, and in due time was delivered of a healthy child. After this, the tumour increased rapidly, and she first began to experience abdominal pains, and difficulty in voiding the fæces. She became pregnant a second time, suffered much during gestation, and had a more difficult labour, but the child was still healthy. She is now 27 years of age, and is suckling; her complexion is dingy, and she is very thin.

The spleen extends from the diaphragm, which it has pushed upwards, in front of and three or four inches below the horizontal part of the os pubis of the left side, where it presents a border of several inches thick, and when this is raised, the patient feels the tumour behind the ribs, pressing against the diaphragm and impeding the movements of the heart. In a lateral direction the tumour extends beyond the linea alba, occupying three-fourths of the whole cavity of the abdomen. Its anterior extent is prodigious, and its tissue apparently very hard. The patient's general health is daily growing worse; she has increasing pains, vomiting, anorexia, constipation, &c. and cannot be expected to survive long.—*Archives Générales.*

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE XLIX., DELIVERED FEB. 7, 1833.

GENTLEMEN,—Every plan for reducing *dislocations of the humerus*, or of the shoulder, as they are called, if it be a good one, must combine three principles, namely, *extension*, *counter-extension*, and the *employment of the shaft of the bone as a lever* for moving its head into the glenoid cavity, and also a fourth principle, which is the *relaxation of the muscles*, as far as this may be practicable, without neglecting the other indications. Yesterday evening I explained the manner of making counter-extension in these dislocations, namely, by means of a girth, or sheet, applied round the chest, and either held by the assistants, or fixed to some point in the direction opposite that in which you are going to make extension. I mentioned, also, the method of fixing the chest, by the assistant holding back the shoulder, and, another mode of fulfilling the same object, by applying a shawl over the shoulder, to be held by the assistants. One caution is necessary, in the application of the means for keeping back the shoulder, which is, that the pressure be not applied so as to lie upon the glenoid cavity, or too near the acromion, for then it would form an obstacle to the return of the bone into its proper situation.

The next thing for our consideration, gentlemen, is the manner of making the extension, and the direction in which such extension ought to be made. I have told you, that, in France, they would generally make extension as far as possible from the joint concerned; thus, in a dislocation of the shoulder, they

would make it at the wrist; but, in this country, the extending means are most commonly applied at the lower part of the humerus itself, and the reason for this is, that British surgeons frequently prefer keeping the fore-arm bent, by which means the biceps is relaxed. They consider, that as the portion of this muscle, attached to the coracoid process, must be stretched when the arm is extended, it would in this state tend to hinder the shoulder from being kept properly back; and, on this account, they keep the fore-arm bent, and apply the extension to the lower part of the humerus. In the plan used in France, they have the advantage of a very long lever, which perhaps fully counterbalances the good derived in our method from the relaxation of the biceps. Before applying the napkin, or cloth, for the purpose of making extension, it is customary to place something immediately round the limb, to prevent the skin from being chafed or too much irritated; and, in this country, it is usual to apply a piece of wet linen, or a few turns of a flannel roller, for the purpose; you then take a piece of strong calico, or linen, which must be three yards long, and half a yard wide, and fold it longitudinally, till it forms a long extending means, about three inches in width. An ingenious way of applying this is mentioned by Mr. Hey in his Surgery, which is rather difficult to describe, though very simple to show; he places the noose first in an elliptical form round the limb, as you see I now place it round my thigh, he then takes one of the ends and passes it over to the opposite side through the noose, then he does the same with the other end, just as I have now done, and the more this apparatus is pulled the tighter it becomes. The contrivance is simple and effectual. Another contrivance is what the sailors call the clove-hitch knot, a drawing of which you will find in Sir Astley Cooper's book. With the cloth, three yards in length, there is, when it is applied, more than a yard left for the assistants to make extension with. When the dislocation is downwards into the axilla, I told you, that the elbow projects considerably

from the side; well, then, extension must be made in the particular direction, in which you find the axis of the bone, that is downwards and outwards, in order to dislodge its head from the inferior costa of the scapula. Now, when you have made sufficient extension in this direction, the next object is to have recourse to the lever-like movement of the shaft of the bone, and, for this purpose, many surgeons place one knee in the axilla, and make a fulcrum of it, and as soon as they see that the head of the bone has been by these means brought sufficiently opposite to the glenoid cavity, the extending power is relaxed, and the muscles draw it into its place. On such principles, the reduction is in general easily effected. If the patient is intoxicated, then you are to take advantage of his condition, in which you may frequently reduce a dislocation without performing any extension at all; indeed, when the person is faint, or intoxicated, if you place the bone over the back of a chair, or over your own knee, the dislocation may be reduced with little or no extension. I have seen this frequently done on drunken persons; and sometimes the bone will slip into its place on the patient moving the arm himself, while it is suspended over the back of a chair, or the mere weight of the limb will be sufficient to effect the reduction.

When the dislocation is forwards, under the centre of the clavicle, the elbow is inclined backwards and downwards, and, if you were to attempt to bring the head of the bone direct from its situation, below the clavicle, into the glenoid cavity, you would fracture the coracoid process, before you could accomplish your object. This shows the necessity of attending to the principle of first dislodging the bone from the situation, in which it has been thrown by the secondary displacement. Now, I have already explained to you, that, in this dislocation, the bone is first thrown out of the glenoid cavity under the pectoral muscles, but does not mount up to its situation under the centre of the clavicle till the secondary displacement takes place. Well, this displacement must first be obviated by pulling the bone downwards and backwards in the direction, assumed by its axis, as one of the effects of the accident. Now, gentlemen, as soon as you have brought the head of the bone below the coracoid process, you must incline the elbow more forwards, and bring it closer to the side; thus you will direct the head of the bone towards the glenoid cavity; at the same time you may use a band, or napkin, placed under the upper part of the humerus, as a fulcrum, for, in this case, you cannot well get your knee under the axilla, so as to make a fulcrum of it. Thus you will easily get the head of the humerus back into the glenoid cavity.

In the other less common dislocation, where the head of the humerus is thrown upon the dorsum of the scapula, the conspicuous prominence of it below the spine of the latter

bone must render the nature of the accident manifest, whether the axis of the humerus be perpendicular, as it sometimes appears to be in this case, or whether it incline forwards, according to the descriptions of various writers. You first, then, make extension in the direction of the axis of the dislocated bone, and afterwards move its head, by means of a roller or napkin placed under the upper portion of the shaft, towards the glenoid cavity. Thus you see, gentlemen, that the reduction of these dislocations of the humerus is performed on the combined principles of extension, counter-extension, relaxation of the biceps, and the lever-like movement of the shaft of the bone. I might add to these the very important principle of dislodging the head of the humerus from the situation, in which it has been thrown by the secondary displacement. When you find a difficulty in effecting the reduction, you will have recourse to debilitating means, such as copious bleeding from a large orifice in the vein, that the patient may become faint, or the administration of tartarised antimony, with the view of bringing on that collapse of the muscular system, which naturally accompanies any severe degree of nausea. Then you will find that, as far as the muscles are concerned, the difficulty of reduction is removed, and the head of the bone, if the case be not an old dislocation, may be readily put into its right place again. Sometimes, in examples of difficulty, the multiplying pulley is used, an instrument which will be shown to you when I come to dislocations of the thigh. After the reduction of the dislocation, the next indication is to take means for preventing the bone from slipping out of the glenoid cavity again. For this purpose a sling is generally sufficient, but for greater security, if the patient be tipsy and restless, you may confine the humerus to the side with a roller.

Dislocations of the elbow.—The displacement of both bones of the fore-arm forwards cannot take place without a fracture of the olecranon, which process of the ulna forms a mechanical impediment to such an accident; indeed, it is an accident of great rarity. On a former evening, I showed you a preparation, in which the olecranon was fractured, and also the coronoid process: and the radius and ulna were dislocated, but not both of them forwards, for the ulna was thrown backwards. The dislocation of the ulna forwards is so uncommon, that few surgeons have seen a case of it. The most common dislocation of the elbow is that in which both bones are thrown backwards, either with or without a fracture of the coronoid process. You see this process affords some resistance to the dislocation backwards; but the accident is not one of considerable rarity, as it is computed, that the dislocation of the ulna and radius backwards is as ten to one in frequency, compared with the lateral dislocations of the same joint. With respect to the frequency of dislocations forward, as compared with that of the dislocations back-

wards, the latter are so exceedingly rare, that no comparison can be made; in fact, the olecranon, unless broken, entirely prevents the dislocation of the ulna forwards.

When the bones of the fore-arm are thrown backwards, I told you, that the coronoid process may not be fractured, and then it passes into the fossa at the back of the humerus, in which the olecranon is naturally situated. On this account the arm cannot be completely extended; the olecranon forms a remarkable projection behind the arm; and the distance between the point of the olecranon and the internal condyle is conspicuously increased; the humerus itself also forms a projection in front of the upper part of the bones of the fore-arm; and the radius is thrown on the outside of, and above the, external condyle. It is of great use, in these dislocations, to attend precisely to the relative positions of the point of the olecranon, and the external and internal condyles; for, sometimes the swelling is so great as to prevent you from making out the case satisfactorily, unless you avail yourselves of these beacons. I mentioned to you, that in the dislocation of the ulna backwards, the distance between the olecranon and the internal condyle is remarkably increased; these points you may always feel in the fattest persons, and however great the swelling may be; therefore there can be no excuse for a surgeon, who does not detect a case of this description.

In this dislocation there is laceration of the capsular ligament, laceration of the external and internal lateral ligaments, and generally, also, of the annular ligament of the radius, which is so closely connected to the external lateral ligament. In consequence of the lower head of the humerus being thrust forwards, the brachialis anticus is liable to be torn; but the tendon of the biceps generally escapes, though tightly applied round the lower articular surface of the humerus. However, if the dislocation has been caused by excessive violence, that tendon may be torn, and even other mischief done; for example, the brachial artery may be ruptured, the median nerve torn, and the veins at the bend of the elbow burst. You will find, in the ninth number of Cruveilhier's great work on *Pathological Anatomy*, which lies on the table, some notice of a case where such complications occurred: it was the case of a lady, who fell from her horse with prodigious force.

The mode of reducing this dislocation is simple:—the surgeon may apply his knee at the bend of the arm, and, taking hold of the wrist, bend the elbow over his knee with the advantage of a considerable lever; the coronoid process will then quit the fossa at the back of the humerus intended for the olecranon, and by continuing the movement of flexion a little further, he will find the bone will come into its right situation. This, you see, is a particular method of accomplishing the reduction; for it does not exactly com-

prise either extension or counter-extension; you merely bend the elbow over the fulcrum of the knee. Now, you will find, gentlemen, if the coronary or annular ligament of the radius is torn, that this bone will be apt to slip out of its place again, unless you take means to prevent it. With this view you must apply a compress over the head of the radius to press it down towards the lesser sigmoid cavity of the ulna; and you are to prevent the radius from moving by applying splints:—two splints, in fact, should be applied, one on the outside, and one on the inside of the fore-arm. If a case of this description remains unreduced, which sometimes happens, nature makes great efforts to repair the mischief; and it is to be observed, that the dislocation is complete, the articular surfaces not being at all in contact with each other. Sometimes, indeed, a surprising attempt is made to form a new socket for the humerus. You see in these plates of Cruveilhier's great work a representation of such a dislocation, and of the efforts made by nature to repair the mischief; a considerable quantity of bony matter has been thrown out to form a socket for the humerus. These plates also show the changes, which take place in the shape of the bones when their functions have been destroyed by remaining long unreduced. In the instance here exhibited, a very limited degree of motion remains; and nature had done all in her power to produce a new articular cavity even for a ginglymoid joint.

Sometimes the dislocation takes place in another way, the ulna being thrown backwards, and the radius forwards; the former bone assuming the position described in the last dislocation, while the head of the radius is propelled forwards. This dislocation is reduced nearly in the same way as the other case which I have already noticed; but you have to make some degree of extension in the first instance, otherwise you could not bend the elbow with the radius in front of the humerus; and after the requisite degree of extension has been made, the bones will return into their proper situations on bending the elbow over the knee.

In other instances, you may have a dislocation of the radius alone; when the radius is dislocated from the lesser sigmoid cavity of the humerus, it is generally thrown on the outside of the external condyle, and sometimes behind it. The nature of the dislocation will be sufficiently obvious, for you will feel the head of the radius on the outer part of the arm; this accident is not very common, but perhaps more so than is sometimes represented; at all events, I have seen three or four examples of it, and there are many instances of it on record. Here is a drawing of one such case, which was dissected by Cruveilhier; the dislocation had not been reduced, and nature had formed a sort of fibrous capsule for the reception of the head of the radius, which capsule Cruveilhier thinks was de-

rived either from the remains of the annular ligament or of the external lateral ligament. This plate also illustrates a circumstance which I pointed out to you in some preparations the other evening, namely, the change which takes place in the articular surface of a bone that has been long out of its place. For the reduction of this dislocation, the best plan is first to make extension of the arm, and to limit the extension as much as possible to the radius; thus you will draw the displaced bone into its proper situation. Now, the head of the radius will be apt to slip out of its place again, unless means be taken to prevent it; you must, therefore, hinder all motion of the radius with splints, and support the head of it with a compress, applied in the manner I have already mentioned. This tendency of the head of the radius to quit the lesser sigmoid cavity after the reduction, is owing to the annular ligament being torn. A child was brought to the Bloomsbury Dispensary about two months ago with this dislocation; the accident had occurred seven weeks before I saw the case, and nothing would avail in keeping the head of the radius in its place; we applied splints for three or four weeks, but at the end of this time, the bone glided into, and out of, the articular cavity as readily as ever. A boy, in attempting to leap over the post in front of my house, fell down and dislocated his elbow; it was a dislocation of the ulna backwards and the radius forwards. I had not the slightest difficulty in reducing the case, which terminated very favourably.

There is one particular dislocation of the fore-arm which I must now mention,—that of the lower end of the ulna from the sigmoid cavity of the radius. It is said to take place mostly from a forcible pronation of the hand, the ulna being then thrown back, and the hand fixed in the position of pronation. There is a possibility, however, of the displacement taking place in the other direction, or of the ulna being thrown forwards and the hand supine; but the first kind of displacement is the most common. Here you are to make extension, and press the displaced bone in the direction required to bring it into the proper position again; afterwards you apply a spint to prevent the radius from moving.

But, gentlemen, what am I to say about *dislocations of the wrist*, more strictly so called, or those which have been generally supposed to occur between the carpus and the radius? A gentleman asked me the other day, if it were true that the wrist was never dislocated? To which I answered, that it was not possible for me to agree in that doctrine, because I had seen a case, in which the lower end of the ulna protruded through the skin. However, his question related to the possibility of a dislocation of the carpo-radial articulation. You will find various anatomical reasons assigned by Baron Dupuytren, why the radius should rather break than be dislocated from the carpus, and he distinctly declares it as his belief, that

there is not in all the records of surgery, an unequivocal specimen of such a dislocation. He had sometimes been called to cases, supposed at first to be true dislocations of the wrist, but which afterwards proved to be only fractures of the radius near that articulation. One or two instances of such mistakes, verified by dissection, are brought forward, in which practitioners of considerable eminence had been deceived. Hence the Baron is led to conclude, that a dislocation of the wrist is scarcely a possible event, and that the accidents, reputed to be such, are in reality fractures of the radius close to the joint, with more or less displacement of the hand. It cannot be doubted, I think, that this is generally the fact; but it would be making a bold assertion to say, that such a dislocation never happens. Great as Dupuytren's experience is, it is merely a drop in that great ocean of experience, to the rich treasures of which the surgeons of every age have successively contributed. Instead of representing a dislocation of the radius from the carpus as impossible, it would, I believe, be more correct to say, that the accident is exceedingly rare. In Sir Astley Cooper's work, there is a drawing of a dislocation of the carpus backwards, which no doubt is particularly uncommon; for when a person falls on his hand while it is extended, the force would almost always much sooner break the radius, than dislocate it towards the palm; but, if the hand were in the state of flexion, so that the back of the hand received the force, then a dislocation might perhaps be a more likely event. Now, it is worthy of your notice, that Cruveilhier had an opportunity of dissecting such a dislocation, in which the radius and ulna had been thrown on the back of the hand, as you see represented in this plate; the patient, Cruveilhier conceives, had fallen on the back of the hand with considerable force. I ought to mention, however, that Dupuytren and Cruveilhier take different views of this preparation, so that further investigations are desirable. In Cruveilhier's book, you will also find an engraving of a case, in which the radius had been dislocated by the contraction of a burn. Sir Astley Cooper mentions a boy, who fell on the palm of his hand, and the carpus was driven backward. I am not therefore disposed to consider Dupuytren's doctrine as completely established; in fact, it is difficult to restrict the effects of external violence on the joints, considering the infinite variety of circumstances, by which they may be modified and influenced. Two years ago, I afforded professional assistance to a poor lad, who fell from the top of a high barn, near my country house at Shepperton, broke his thigh, and, I am inclined to think, dislocated his wrist. At all events, the little pain experienced in the part after the reduction, makes me suppose that the case could not have been a fracture.

Gentlemen, if you were to meet with a dislocation of the radio-carpal articulation, you

would find it easy of reduction, as all dislocations of ginglymoid joints usually are; the extension and counter-extension need only be made in such a degree as is sufficient to diminish the friction between the articulating surfaces, and then you are to have recourse to pressure on the displaced bones in the direction calculated to bring them into their right situation again. Thus the reduction is readily accomplished. Of course, extension and counter-extension would be necessary, if the dislocation of the carpus were forwards, and you would also have occasion to use splints, for otherwise the movements of the hand might bring on a return of the dislocation, and prevent the speedy union of the ligaments.

Dislocations of the bones of the carpus from one another.—The bones of the carpus are not very liable to be dislocated from one another: however, there is one in the second phalanx, which is occasionally thrown out of its place,—I mean the os magnum. This bone, as you are well aware, is received into a deep cavity formed by the scaphoid and lunar bones, and when the hand is violently bent, it will sometimes start out of this cavity, and form a considerable projection at the back of the wrist. The reduction is occasionally difficult; but, if the bone be left unreduced, there will not be much inconvenience,—there will only be a slight weakness of the wrist. Thus, in one instance, which was attended by Sir Astley Cooper, the inconvenience, resulting from the non-reduction of the dislocation, was that the young lady, who was the subject of it, could not practise music—she could not play on the piano-forte. The case will be evident from the situation of the bone, and its projection beyond the other bones of the carpus. The accident chiefly occurs in children and females, from the greater weakness of their ligaments, and also from the cavity of the scaphoides and lunare being not so deep in them as in male adults. When you attempt to reduce this dislocation, you are to bring the hand into the extended position, and then press firmly on the projecting bone with your thumb. The common plan of palliating this dislocation when it cannot be reduced, is to apply a compress and bandage over it, or straps of adhesive plaister.

The metacarpal bones can hardly be separated from one another, except by great and direct violence, and so closely are they tied together and to the carpus, that scarcely any thing, except gun-shot violence, the bursting of a fowling-piece, or pistol, or the fall of some ponderous thing on the hand, can dislocate them. However, the metacarpal bone of the thumb is more frequently dislocated than any other; and you would suppose, from its having motion in every direction, that it might be dislocated in four directions, namely, inwards, outwards, forwards, or backwards; but experience proves, that it is ordinarily dislocated only forwards or backwards. When a person falls on the radial edge of his hand, and the

thumb is carried violently inwards, the head of the metacarpal bone will be thrown on the back of the trapezium. In other instances, the displacement is in the opposite direction, and the head of the metacarpal bone of the thumb is then thrown between the metacarpal bone of the fore-finger and the inside of the trapezium. The reduction is very easy: the principle is to make counter-extension from the wrist, and extension from the thumb, and to press the bone in the proper direction. But I have one observation to make, which is, that if you do not reduce the bone in the first instance, you may afterwards be baffled; or if you do not keep it reduced for a certain time, you will not effect a cure,—the bone will ever after be subject to slip out of its place.

The next dislocation, gentlemen, I shall have to detain you with some little time, though the joint is but a small one; I allude to the dislocation of the first phalanx of the thumb from the metacarpal bone. With this subject, then, as our time is expired, I will go on to-morrow evening at six o'clock, immediately after Dr. Elliotson's lecture.

CLINICAL LECTURES,

DELIVERED AT THE

HOTEL DIEU, IN PARIS,

During the Session of 1832–33.

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

PATHOLOGY AND TREATMENT OF BURNS.

(Continued from p. 808, Vol. III.)

FOURTH CASE.—Burns of the first four degrees of several regions by boiling soup, and from a pan of burning coals. Death during the period of re-action—Angelica Francis Bisson, aged forty, subject to epilepsy for several years, was sitting close to the fire when attacked by a fit; she fell on a pot of boiling soup. The left side of the face and the whole of the right hand were burned in the first and second degrees; the left elbow and the superior and left lateral parts of the chest, which had been in immediate contact with the brasier (pan of coals), were burned in the third and fourth degrees.

The burn of the first degree was marked by extremely vivid redness, that of the second by numerous phlyctenæ, and those of the third and fourth degrees by large and deep eschars. Unfortunately all these burns were very extensive: the patient was in a state of general anxiety, and uttered the most piercing cries from extreme suffering. She had very frequent and severe fits of convulsions, and was at times delirious. (Bled freely, opiate potion, diluting drinks, simple diet, fine linen spread with ointment, charpie, and poultices.)

During three days the patient did well. On the fourth all the symptoms were increased;

pain aggravated; delirium almost constant; erysipelatous redness over the whole body; tongue red and dry; very great anxiety. She was again bled, but the symptoms increased, and in the course of that day she died.

Necropsy.—The pia mater and the substance of the brain were slightly injected, the mucous membrane of the stomach and bowels inflamed in several parts, and the inner coats of the veins were remarkably reddened.

FIFTH CASE.—*Burns of different degrees from the ignition of the apparel. Tetanus produced by the inflammatory reaction.*—

Death.—Roger J. B., aged thirty three, a day labourer, came to the Hôtel Dieu, suffering for two days from the effects of a large, deep burn, produced by the combustion of his clothes, while in a state of intoxication. The burn occupied the posterior sides of the thigh, both externally and internally, extending from the bend of the hip to the ham. The sphacelated skin on the greater part of the surface, was dry, hard, and crepitous. Around the eschar, the burn was of less intensity, and the different degrees could be easily distinguished, forming a sort of zone, of about two inches and a half in extent. The pulse was rather weak. Nevertheless bleeding was ordered, and emollient cataplasms applied to the eschar.

On the fourth day from the accident, the febrile reaction was more marked (baths, anodyne cataplasms, sedative potions.) On the sixth day, the eschar was softened, an inflammatory tumefaction surrounded all the parts, and granulations appeared, but the patient suffered the most excruciating agony, and was tormented with want of sleep; the pulse was very frequent.

On the ninth day, there was headach over the frontal region, and on the tenth the pains were very severe. The jaws more nearly approached each other; stiffness in the neck and the right arm; belly painful, and sensible to pressure; skin hot; pulse frequent, (he was bled from the arm in the morning, and fifteen leeches were applied behind the ears; sedative potion, with fifteen drops of laudanum.) Every care was taken in dressing the wounds, that they should be exposed the least time possible to the air. On the eleventh day he was worse and wakeful; his arms, neck, and jaw were stiffened, and it was with difficulty that he could at all separate the latter. Profuse perspiration; pulse contracted; was bled to syncope; bath of three hours; anodyne injection and potion, and anodyne embrocations to the jaws and muscles of the neck.

On the twelfth day the neck was thrown back, the muscles of the pharynx were contracted, and he was insensible at times. On the thirteenth day all the symptoms were aggravated; body bent backwards by the contraction of the muscles, and profuse perspiration; pulse hard and frequent; no delirium. Wounds

dressed with opiate cerate; six drops of laudanum in injection every two hours; anodyne embrocations over the body continued. Suppuration from the wounds not very great; burnt surfaces raw. Pain of the neck greatly increased on the slightest pressure, and likewise over the epigastrium; respiration difficult; symptoms becoming more alarming, twenty-five leeches to the back of the neck. The patient continued, until this day, to pass his fæces and urine naturally, and was sensible. Pulse scarcely to be felt. He died at seven o'clock p.m.

Necropsy.—Thirty-six hours after death those parts of the body not affected by tetanus were stiffened, but the muscles of the neck and shoulders, and generally wherever tetanus had existed, were relaxed. On the thigh was a square foot of surface where the skin had sloughed away: the wound looked healthy. The veins on the inner part of the skull were gorged with blood. The arachnoid had a light bluish tint, and was with difficulty detached from the grey substance of brain, which was injected with blood, and of a red colour, and exuded some blood upon pressure. The white substance of the brain was likewise injected with blood, which diminished towards the ventricles, where all trace of it was lost, and but little serum was found in them. Some vessels considerably injected were seen running on the surface of the *corpora striata* and the optic canals. Internally, however, their vascularity was not remarkable; the brain was otherwise of a pretty firm consistence. The spinal veins were gorged with black blood; the marrow was of its ordinary consistence. A few inches below the cerebellum and even with the eighth or ninth dorsal vertebra, the grey substance of the spinal marrow was found injected in the same manner as the brain. A slight redness was found near the fundus of the stomach, over the ilium and ascending portion of the colon; liver and spleen healthy; the bronchiæ were healthy; the lungs slightly adhered posteriorly by some old adhesions, and were loaded with blood. The heart and vascular system were in a healthy state. Nothing particular was remarked in the genito-urinary organs.

SIXTH CASE.—*Burns from the first to the third degree, diffused inflammation coming on at the period of re-action, followed by symptoms of gastro-enteritis and meningitis.*

Death.—A female servant, named Magia, aged sixty-three, of weak constitution and bad health, was seated by a wood fire, near which was a pan of burning charcoal. The smoke from the latter made her giddy; she fell into the fire, and severely burnt her right heel and buttocks. When brought to the Hôtel Dieu there were no traces of asphyxia, but she complained of great pain in the burnt parts; there was a large, hard, and white eschar on each buttock, surrounded by phlyctenæ, (of the second and third degrees,) a bright erysipela-

tous redness spread over the thighs and posterior parts of the body (of the first degree); under the right heel was an eschar of the size of a crown piece; the calf of the leg was red and erythematous, and in other parts were phlyctenæ, filled with serum (first, second, and third degrees). Bath; fine linen spread with ointment applied to the parts; anodyne potion. During the night she was restless, in the morning complained of severe headach, for which she was bled from the arm. On the third day the burnt parts were extremely painful. From lying so constantly on her back it was feared the burnt parts would become gangrenous; she was, therefore, ordered to lie on her stomach. On the fifth day, the eschars began to separate at their edges, and did not appear very deep; she frequently asked for food, which it was not thought prudent to allow her. In the evening, rigors and fever supervened, with pain in the right leg. The burns of the first and second degree were nearly healed, and were affected by inflammation, and the affected limb was swelled and erysipelatous. On the sixth day, the inflammation put on the appearance of diffused phlegmon, extending to the upper part of the thigh: the knee was very painful. General bleeding it was feared would lower too much the powers of the system; twenty leeches were therefore applied over the limb. For thirty-six hours the phlegmon appeared stationary, but delirium soon came on; the features contracted; the mouth and lips grew parched; the fever more severe; vomiting and diarrhoea ensued, and she died on the eleventh day from the accident. On examining the body, thirty six hours after death, in the brain the ventricles contained a large quantity of red serum, and the arachnoid was inflamed. The base of the right lung was hepatized; the bronchial tubes were injected, and filled with thick mucus; a slight effusion was found in the right pleura; the heart was enlarged; its cavities were enlarged; and its walls thinner than natural; slight traces of old inflammation were found on the mucous surface of the pericardium. The mucous membrane of the stomach was reddened; the gall-bladder contained about thirty gall stones; the mesentery was tuberculated; the liver enlarged, and loaded with fat.

SEVENTH CASE.—*Asphyxia from charcoal—Second and third degree of burns from vestments burning—Unusual state of wound—Different circumstances happening after suppuration—Death at the end of eight months.*—The history of this case is remarkable, as presenting a different terminating result of burns not very rare, where the patients, after a shorter or longer space of time, from the system not having sufficient power to support nature during the process of cicatrization, after suffering from many unforeseen circumstances occurring.

Marie Ponchu, aged 42, was throwing some water over a fire, and fainted. Her clothes

were burnt; large phlyctenæ were spread over the lower part of the back, and the skin of the ham was torrified. In four or five days large eschars covered the burnt surfaces. On the eighth day there was a discharge of blood from the ulcerated parts; they were extremely painful; suppuration very great; the pulse was feeble and small, and the patient threatened to sink. Tonics were prescribed. She bore her sufferings with remarkable patience; the extensive suppuration was checked with difficulty, and the cicatrization proceeded slowly. Many unforeseen circumstances now occurred; attacks of erysipelas, collections of matter in the joints, with symptoms of gastric irritation. The patient from these divers causes soon sunk into a state of extreme feebleness and exhaustion, and died eight months and thirteen days after the accident, the cicatrization of the ulcers at that time being very nearly completed. This case offers an example of the longest period that a patient can survive after an accident of this kind.

EIGHTH CASE.—*Burns of the feet from the first to the fourth degree from a pediluvium—Diffused phlegmon—Death on the seventh day.*—A lace-woman, aged 17, of good health, learning that a marriage, which she was to have contracted with a young man, was set aside, conceived the idea of destroying herself. Shut herself in a narrow chamber, in which were two pans of burning charcoal. She grew insensible, and none knew how long she remained in that state. A person who was coming to see her, hearing deep moans in the room, burst open the door, and found her in a state of apparent death. The surface of the body was purple; respiration and pulse at the wrist scarcely perceptible, but the temporal arteries could be felt beating feebly. The patient was put near an open window, the body rubbed with warm vinegar, and she showed some signs of returning life. A vein in the arm was opened, the blood soon flowed, and three cups full were taken away with great benefit. A mustard pediluvium was ordered instead of one at the ordinary heat, 30°; by some mistake the attendant put the patient's feet into hot water at 100°. In the course of half an hour she began to speak, complained of the heat of the water and of fullness of the feet, and was placed in bed. On the following morning she was greatly agitated, complained of violent pains in the legs: both the feet were then found to be burnt to the height of three fingers' breadth above the malleoli, the toes were deprived of epidermis, the insteps and ankle-joints were covered with yellow hard eschars; at the lower part of the leg the edges of the burn were marked by numerous phlyctenæ filled with red serum, the upper part of the leg was tumefied, red, and painful. On the third day all traces of asphyxia were absent, but the vital functions were much depressed, pulse was small and weak, eyes dull, and patient very low. The burnt parts were

covered with fine dressing, and enveloped in poultices, and laid upon pillows. On the fifth day the legs were much inflamed, and thirty leeches were applied to each; bath. On the sixth day an obscure fluctuation was detected in the right limb, the phlegmon had spread to the knee and thigh; delirium came on, and she sank on the seventh day.

Necropsy.—Some of the eschars were commencing to separate at their edges. All the joints, especially the ankles, were inflamed; the synovial membrane was red and injected; in the right ankle there was an effusion of red serum. Below the burnt surfaces the skin was destroyed to some extent; and in the right limb an abscess was detected, and the matter burrowed up among the muscles, dissecting them nearly to the knee. Matter was also found infiltrated among the muscles of the thigh, and over the inferior and posterior parts of the trunk; the cellular tissue was every where thickened, the brain and its meninges were injected. The above unsuccessful cases have been selected, in order to show from what causes death ensues at different periods of time after the burn, and what are the anatomical characters after death. What are the most remarkable and instructive points connected with the foregoing seven cases? In all of them the burns were of a most severe nature, spreading more or less. In the two first cases they occupied nearly the whole of the body; in the second and third cases, also, the patients sunk under a general state of irritation,—one, aged three years and a half, in a few hours; the other, thirty years old, on the second day. In the fourth case, the patient could not resist the inflammatory action, and died on the fourth day with violent symptoms of inflammation of the brain and digestive organs; the fifth died from a severe tetanic affection on the twelfth day; in the sixth and eighth cases diffused phlegmonous inflammations ran on to extensive suppuration, separation of the cutis to a great extent, inflammation and suppuration of the joints which, reacting upon the internal organs, caused death in the one case on the eleventh day, in the other on the second. In the seventh case many unfortunate circumstances occurred during a period of eight months; suppuration went on during the whole period; the cicatrization could not be completed, and she sunk into a state of marasmus.

Burns have been at all times attempted to be cured by empirics. Every period of time has had its peculiar remedy, which has fallen into disuse, and given way to others. Nothing can check the researches of these persons after a *certain and infallible* cure for burns.

EIGHTH CASE.—A young woman was brought to the Hôtel Dieu some years since, whose extensive burns extended nearly from head to foot. From the complete insensibility of the burnt parts, the destruction of the epidermis, the disorganisation of the mucous

tissue, and the darkened yellow appearance of the chorion, it was easy to determine that the skin throughout its whole thickness was affected. From the weakness of the voice and pulse, the insensibility and death-like appearance of the body, it was highly probable that death would soon ensue, or that if she escaped through her present dangerous condition she would not be able to resist the effects of the secondary inflammation, and that, in either case, her constitutional strength would not support her through the process of suppuration, still less through the healing of the cicatrix. A lady, respectable by her manners and address, accompanied the patient, and with great zeal and importunity requested to be allowed to treat the case by a plan of her own, which had already cured numberless cases of severe burns like the present. M. Dupuytren represented to her that the patient was suffering under a dreadful burn, which doubtless would prove fatal; yet, in spite of this, the lady urged her suit so strongly, that she was permitted to treat the patient by her own method. This she did during four days with great assiduity and zeal. Circles of inflammation appeared on several parts of the burnt surface from the ointment that was used, and large portions of skin were detached; yet the lady was nothing daunted, until the death of the patient, on the fifth day, threw some doubts over her mind as to the reputed efficacy of her remedy.

The reason, continued M. Dupuytren, why such confidence of successful treatment is shown on the one hand, and such implicit credulity on the other, is from the circumstance that a burn is considered as a simple affection in its nature and phenomena, constant in its course and effects, and which, therefore, may be easily cured by a remedy simple as it is supposed to be itself. So far from a burn being a simple affection, it is one very complex, of which the various degrees constitute so many affections, presenting single characteristics, variable effects, and particular complications, and of which the treatment of each is essentially different. It is requisite to remember the different effects of heat on the living tissues to be convinced of these truths. It will be only necessary to bear in mind the natural and immediate effects of the action of caloric; the consecutive effects of which they eventually become the cause; the suppurative and ulcerative stages of inflammation, the local and general fever, the numberless complications accompanying them, the various accidents which may follow them, such as pain, spasm, convulsion, and tetanus; the cares requisite to retard the formation of a cicatrix, to prevent deformity in certain cases, and to hasten its formation in others in order to prevent death, to be convinced of the folly of using secret and infallible remedies in the treatment of such cases. A perfect knowledge of the organisation of parts, and the changes they may undergo, and great experience in the use of

those remedies necessary to re-establish their natural state, can alone lead, with any certainty, to a healthy cure.

The treatment of these lesions depends upon the following indications:—

1. To remove the cause of the burn.
2. To avert the inflammation, to moderate in the two first degrees the pain and cutaneous irritation at the time of the accident, and to prevent their effects on the internal organs.
3. To restrain to a certain limit the secondary inflammation caused by the separation of the eschars and the coming on of supuration.
4. To aid by the greatest care the cicatrization of the after wounds.
5. To prevent the contraction or false adhesion of any part of the cicatrix which might prevent due motion or a proper exercise of the functions of the part.
6. To avert the general primitive and consecutive accidents which may arise in the course of the disease.

The power of removing the cause of the injury never presents itself to the surgeon but in cases of burns produced by caustic, of which an unassimilated portion yet rests upon the surface, and this may be done by those substances in the form of lotion which chemistry teaches us will neutralise the burning substance. In the majority of cases, simple water will effect this purpose. In burns of the first degree, or in those of the second, in which the epidermis is denuded, all the care of the practitioner should be to avert the inflammation, and prevent the formation of phlyctenæ or scars, which might tend to increase the difficulty and time of cure. Light astringent applications, sedatives, and non-excitants are the best means to promote this end. Immersing the parts in cold water, Goulard water, or water with a small quantity of spirit or vinegar in it, are valuable means, and when this is not practicable, the frequent fomentation of the parts with the same liquids, or with ether, alcohol, or a solution of sulphate of iron or alum, potash or ammonia are of great value; these last means, however, can only be employed where the epidermis has not been abraded, where it has, they only augment the irritation, and induce severe pain. It becomes, therefore, of importance, that the epidermis should be kept entire, and those portions of the dress covering it should be removed with the greatest care. If there should be any phlyctenæ they should be opened with a fine needle, or the point of a lancet at the most depending point. Should the pain and irritation be very great, anodyne potions may be given with advantage. If the patient is young, vigorous, and plethoric, local or general blood-letting will be very soothing, and tend to prevent inflammation; the means used will prove more successful in proportion as they are administered soon after the occurrence of the accident; the more severe the injury the lower should be the diet allowed. Mucilaginous, diluent, and acidulated drinks

will be useful. If, in spite of all effort, inflammation should ensue it should be moderated and prevented from reaching the healthy tissues, or, if excessive, from terminating in gangrene, or from re-acting with too great violence upon the external organs. In such a case emollient and anodyne fomentations, and general and local blood-letting should be practised. In addition to these, if the pains should be very intense, anodyne balsams. Rousseau's laudanum, decoctions of nightshade, henbane, or poppy heads should be made use of.

The same indications again present themselves in burns of the third and fourth degrees, when the secondary inflammation occurs; if too violent it should be repressed, if too weak it should be stimulated. It should not, however, be forgotten, that, in these cases, excitants, if too long continued, are very apt to terminate in erysipelas, commencing on the edges of the wound, and spreading thence over a great part of the body, and in some cases proving mortal. This has been frequently arrested by applying a blister for a short time over the part itself. A light covering of charpie to absorb the discharge, should be placed over the wound, and over that some fine lint, imbued with some cooling, simple, or saturnine ointment. Emollient cataplasms should be placed over the eschars to facilitate their formation. When they are nearly detached they may be removed with the scissors. In some cases where the eschar is deep, as in burns of the fourth and fifth degrees, pus will collect beneath them. This may be ascertained by a sense of fluctuation. They should be punctured immediately, to prevent the infiltration into the surrounding cellular substance. If on the separation of the cutis forming the phlyctenæ the skin beneath should be very painful, opiate cerate, or linen imbued with a solution of extract of opium will be found to be the best remedies.

The wounds should be dressed quickly, that they may be exposed to the air as short a time as possible, and with great gentleness to avoid giving unnecessary pain to the patient. In some cases, especially in burns of the fourth and fifth degrees, the suppuration is generally so abundant as to require the sores to be dressed three times daily. In these cases the patients fall into a state of deplorable weakness, which should be guarded against by administering tonics, such as the quinine, both by the mouth and by lavement. When there is much substance destroyed by a burn, the cicatrix will sometimes be greatly contracted; this should be guarded against by preventing the cicatrix occupying less room than the skin it covers, and drawing in the edges too much. This may in general be done by cauterising carefully the superabundant granulations by the position of the limb, by careful dressing, and by solid support. Thus the patient should not bend the limb if the burn is in the seat of flexion, or extend it if the burn should be

stretched by that means; and tents and sponges should be introduced to prevent the cicatrix narrowing too closely. Compresses and other means should be employed to prevent parts, such as the fungus, from contracting vicious adhesions. In the face, where the parts are so moveable and extensible, it is not always possible to prevent a slight deformity; the contracting edges may be here separated as wide apart by plasters and other contrivances as possible; but where a good cicatrix can only be formed at much expense of pain to the patient, it should be avoided. When a limb, or part of a limb is destroyed, amputation becomes necessary. In this manner a wound will be formed, the discharge from which will be soon over, and the cicatrization simple and easy for an eschar, the effects of which will be long felt, and which will leave behind it an irregular solution of continuity, with a projection of bones and other substances, which, situated more or less deeply, have been subject to the action of the fire. Besides, in removing the burnt parts, the patient is preserved from the secondary inflammation. Nevertheless, the surgeon should take into consideration the constitution, age, and strength of the patient, and whether he will be able to go through the operation. It should also be remembered, that if the patient be in a state of stupor, as sometimes happens, or if the local inflammation has set in, or if fever be present, these must be allowed to subside and suppuration to be established, and the general state of the patient, and the appearance of the wound be afterwards taken to guide our conduct. After the cicatrices have formed, the parts preserve a degree of stiffness which does not permit of the free exercise of their functions. Fomentations, frictions, oily embrocations, and stupes should then be used.

The patient should at first move about but very slowly, lest the cicatrices should give way, which is sometimes the case when they are on the abdominal extremities. A slight burn, which does not materially affect the internal organs, will require no internal medicine. But even if it be superficial, and occupy a large surface, the patient should, upon principle, be kept upon a strict diet, by emollient and refreshing drinks, and kept in some quiet spot, away from all moral and physical excitement; and these means alone should be employed if the burn be deep. Severe pain and suffering should be relieved by opium in large doses; fever and any inflammatory action should be treated by bleeding, especially if the subject be strong and plethoric; this, however, should not be carried to any great extent; if the depth of the burn makes it probable that there will be an abundant suppuration, for in such a case the bleeding will weaken him, and he will not be so well able to bear up against the suppuration, and he would sink from exhaustion. Suppuration being established, and the fever subdued, light and nutritious diets may be given, but in small quantities. If the

suppuration be very great, and of great extent, threatening the patient with marasmus, preparations of steel and quinine will be appropriate. If there is marasmus and colliquative diarrhoea, a pill, composed of half a grain of gummy extract of opium and one grain of sulphate of zinc, may be given three or four times daily.

TENTH CASE.—Epileptic—Burns from the third to the fourth degree on the posterior surface of the right inferior extremity—Perfect cure on the hundred and forty-fifth day—No attack of epilepsy during the treatment.—Desirer Lampet, aged thirty-six, subject to epilepsy from her infancy, was shut in a chamber where was a furnace full of lighted charcoal. She soon became giddy and fell upon it, and the back of the right inferior extremity remained exposed for a certain time to the flames. There was a burn of the third and fourth degrees, which extended from the upper part of the thigh to half way down the leg, and enveloping more than half the circumference of the limb, especially around the upper part of the popliteal space. The skin, cellular tissue, and the superior surface of the muscles, were dead. Compresses spread with ointment, and antispasmodic drinks, were administered. During the first seven days she remained at home. Inflammation had already commenced, and the line of demarcation between the dead and living parts was visible, and large eschars were formed, and seemed but slightly attached to the limb when she entered the Hôtel Dieu. Compresses spread with ointment, charpie, emollient cataplasms and soothing drinks, were the means used. At the end of three days all the eschars had separated, and beneath was seen a reddened vermilion surface of wound covered with healthy granulations. The same treatment was continued; but lest some cicatrised circles should form, and controul the motions of the limb, making it deformed, it was placed on an inclined plane. The limb was thus properly stretched that the cicatrix might form every where regularly. The suppuration was very great, and the wound was dressed twice daily. This, however, decreased in a short time, and the cicatrix gradually advanced over the wound; this was soon checked by the superabundant growth of granulations, which, although the nitrate of silver was used to them, grew up so rapidly that, notwithstanding all care, the cicatrix was only formed at the end of 145 days. The limb lost nothing of its natural shape, and in the course of time the patient recovered the free use of it. During the whole time she was in the hospital she had not one epileptic attack.

COPY

OF THE REGULATIONS AND BY-LAWS
OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON;

With Tables of the number of Fellows and Licentiates admitted Jan. 1, 1823, and Dec. 31, 1832, and the Cash Accounts connected therewith.

PHYSICIANS' COLLEGE.

RETURNS TO SEVERAL ORDERS OF THE
HONOURABLE HOUSE OF COMMONS,
Dated June 21, 1833.

No. I.

A Copy of the Regulations or By-laws under which the Graduates in Physic have been admitted as Fellows of the Royal College of Physicians of London, since the year 1771.

DE ORDINE CANDIDATORUM.

I.—Nemo in Candidatorum ordinem admittatur qui non in omnia Britanniarum Jura natus est, vel qui munus Collegii quodvis exequi per statuta Regni prohibitus est.

II.—Nemo in Candidatorum ordinem admittatur qui non annum ætatis suæ vicesimum sextum clauserit.

III.—Nemo in Candidatorum ordinem admittatur nisi qui in Academiâ vel Oxoniensi vel Cantabrigiensi Medicinæ Doctor creatus fuerit, idque postquam omnia in Statutis utriusvis Academiæ præscripta compleverit, sine dispensatione vel gratiâ insolitâ. Si quis verò Doctoratus gradum in Academiâ Dublinensi adeptus fuerit, volumus ut antequam eligendus proponatur, literas testimoniales tam ab illâ Academiâ, de præstitis omnibus exercitiis ibi necessariis sine dispensatione vel gratiâ insolitâ, quam ab alterutrâ Academiarum prædictarum de corporatione suâ Registrario proferat. Illos vero qui in prædictis Academiis vel honoris causâ, vel ex mandato qualicunque aut privilegio extraordinario, Medicinæ Doctores creati fuerint, gradus istiusmodi virtute in Candidatorum ordinem cooptari nolumus.

IV.—Nemo in Candidatorum ordinem admittatur qui medicamentum quodvis arcanum (nostrum vulgò dictum) in morbis curandis ad quæstum usurpaverit, aut qui Pharmacopolæ vel Obstetricis arte aut mercibus quibuscvis vendendis victum quæritaverit, nisi gravi aliquâ de causâ Comitii Majoribus approbandâ aliter visum fuerit.

V.—Nemo in Candidatorum ordinem admittatur qui non ante examinationem primam omnes Socios in Urbe et Suburbis habitantes gratiæ impetrandæ ergo, visitaverit.

VI.—Nemo in Candidatorum ordinem admittatur qui non prius examinatus et approbatus fuerit in tribus Comitii, sive Majoribus sive Minoribus pro arbitrio Præsidentis, aut Propræsidentis, et Censorum, aut eorum majoris partis secundum hanc formam :

FORMA EXAMINATIONIS.

VII.—Unusquisque eorum qui in ordinem Candidatorum admitti petat examinatur,

In primis Comitii in parte Medicinæ Physiologicâ;

In secundis in parte Pathologicâ;

In tertiis in parte Therapeuticâ;

Præterea examinatur in Græcis literis, ad Medicinam spectantibus; scilicet in Hippocrate, vel Galeno, vel Aretæo. Proponantur cuiuspiam in primâ examinatione loci ex Aphorismis Hippocratis vel à Galeno; in secundâ et tertiâ examinatione loci ex Hippocrate, vel Galeno, vel Aretæo, qui Latine reddantur, et brevi Commentario illustrentur. Singulæ examinationes prædictæ Latine fiant. In singulis Examinationibus, sive in Comitii Majoribus sive Minoribus fiant, liceat cuilibet Socio pro Arbitrio disputare et periculum facere quantum examinandus in re medicâ valeat.

VIII.—Qui ad hanc formam in Comitii Minoribus examinatus, et à Præsidente aut Propræsidente et Censoribus, aut, uno Censorum absente, à Præsidente aut Propræsidente tribus Censoribus et absentis Censoris vicario aut eorundem majore parte suffragiis per pilas occulte acceptis in utrâque examinatione approbatus fuerit, in Comitii Majoribus proximè insequentibus proponatur in ordinem Candidatorum admittendus, et si major pars Sociorum præsentium consenserit, peractis iis ab ipso, quæ per statuta nostra requiruntur, quamprimum admittatur.

IX.—Qui vero in Comitii Majoribus examinatus fuerit, si in singulis Examinationibus se idoneum præstiterit majori parte Sociorum præsentium, à tertiâ Examinatione statim proponatur in ordinem Candidatorum admittendus, et si consenserit major pars Sociorum in illis Comitii præsentium, peractis iis ab ipso, quæ per Statuta nostra requiruntur, quamprimum admittatur.

X.—Si verò quiespiam in utrâvis Examinationum prædictarum à Præsidente vel Propræsidente et Censoribus, vel uno Censorum absente à Præsidente vel Propræsidente et Censoribus præsentibus, et absentis Censoris vicario, aut eorundem majore parte, suffragiis per pilas occulte acceptis, minus peritus, nec ad facultatem Medicinæ in urbe Londino et intra septem milliaria in circuitu ejusdem exercendam idoneus existimatus fuerit; à Præsidente vel Propræsidente coram Censoribus præsentibus, si in Comitii Minoribus, sed coram Sociis, si in Comitii Majoribus examinatio fiat, admonetur, ne medicinam in dictâ urbe aut per septem milliaria in circuitu ejusdem exerceat, donec Sententiâ Præsidentis vel Propræsidentis et Censorum peritior et satis idoneus existimetur; et non nisi præterito integro anno ad examinationem iterum admittatur.

XI.—Antequam quiespiam in Candidatorum ordinem admittatur det fidem infra scriptam Præsidenti aut Propræsidenti coram Sociis præsentibus in Comitii Majoribus Comitii: "Dabis

fidem te observaturum statuta Collegii, aut multas tibi contra facienti irrogandas promptè persoluturum; et pro viribus conaturum ut honor ejus integer conservetur; omniaque in arte medicâ facturum in reipublicæ utilitatem."

XII.—Quam fidem literis mandatam quilibet Candidatus, postquam admissus fuerit, insuper confirmet nomine suo subscripto.

FORMA ADMISSIONIS.

XIII.—Admittendus flexis genubus manus invicem applicatas humiliter tradat in manus Præsidentis vel Propræsidentis qui dicat:—"Ego A. B. Præsidentis vel Propræsidentis, hujus Collegii admitto te in ordinem Candidatorum precorque tibi omnia fausta."

XIV.—Omnes Candidati tempore admissionis suæ literas habeant sigillo Collegii munitas sub hâc formâ:—

"Sciant omnes Nos. A. B. Medicinæ Doctorem et Præsidentem Collegii Medicorum Londinensis una cum consensu Sociorum ejusdem auctoritate nobis à Domino Rege et Parlamento concessa, examinasse, approbasse, et admisisse in Ordinem Candidatorum, doctum et probum virum, T. S. in florentissimâ Academia..... Doctorem eique concessisse liberam facultatem et licentiam exercendi scientiam et artem medicam juxta formam Statutorum ad hoc editorum.

"In cujus rei fidem et testimonium sigillum nostrum commune præsentibus apponi fecimus.—Datum Londini..... die Mensis..... Annoque Domini....."

XV.—Si quis postquam in ordinem Candidatorum fuerit admissus, Pharmacopœæ aut Obstetricis arte aut Mercibus quibusvis vendendis victum quærivaverit, statuimus illum è Candidatorum ordine excidisse.

XVI.—Si quis Candidatus criminis alicujus gravioris ac publici damnatus fuerit, è Candidatorum ordine expellatur, si ita visum fuerit majori parti Sociorum in Comitibus Majoribus præsentium, suffragiis per pilas occultè acceptis.

XVII.—Si quis Candidatus medicamentum quodvis arcanum (nostrum vulgò dictum) venditaverit, et delicti hujus à Præsidente et Censoribus, aut eorum majore parte convictus fuerit, è Candidatorum ordine, si ita judicatum fuerit à majore parte Sociorum in Comitibus Majoribus præsentium, suffragiis per pilas occultè acceptis expellatur.

XVIII.—Nullus Candidatus à Præsidente in Comitibus Majoribus ad eligendum in ordinem Sociorum proponatur, qui non in ordine Candidatorum benè se gesserit, et secundum Statuta Collegii se idoneum præstiterit.

Quandoquidem nonnulli sunt quibus propter licentiam ad practicandum in Medicinâ ab Academiâ sive Oxoniensi, sive Cantabrigiensi, per totam Angliam præter Urbem Londini et intra septem Milliariæ in Circuitu ejusdem per Statuta Regni licet Medicinam exercere, nullâ

coram nobis habita Examine volumus, præmissis non obstantibus, ut unusquisque eorum qui annum octavum a primâ Commoratione suâ in alterutrâ Academiarum prædictarum compleverit, et Annum Ætatis suæ vicesimum sextum clausierit, et ea quæcunque de Ordine Candidatorum præscripta fuerint, præter Doctoratûs in Medicinâ Gradum præstiterit, postquam in tribus Comitibus, sive Majoribus sive Minoribus, pro arbitrio Præsidentis et Censorum aut eorum majoris partis secundum formam de Candidatis dictam examinatus et approbatus fuerit, admittatur ad Medicinæ Facultatem exercendum in Urbe Londino et intra septem Milliaria in circuitu ejusdem si ita visum fuerit majori parti Sociorum in Comitibus Majoribus præsentium, suffragiis per pilas occultè acceptis; volumus quoque, ut Locum infra Medicinæ Doctores in Ordine Candidatorum occupet, nomine Candidati Inceptoris designatus.

Si quis verò ita admissus Gradum Doctoris Medicinæ in alterutrâ Academiarum prædictarum intra triennium non susceperit, statuimus et ordinamus illum è Candidatorum ordine excidisse, nisi gravi aliquâ de Causâ aliter visum fuerit majori parti Sociorum in Comitibus Majoribus præsentium.

DE SOCIIS.

I.—Nemo in Sociorum ordinem admittatur, qui non fuerit aut annum integrum Candidatus postquam Doctoris Medicinæ gradum susceperit; secundum formam de Candidatis dictam, aut è Permissorum numero electus, ut postea statutum est.

II.—Nemo in Sociorum ordinem admittatur, qui non in omnia Britanniarum Jura natus est, vel qui munus Collegii quodvis exequi per Statuta Regni prohibitus est.

III.—Nullus Candidatus in Sociorum ordinem admittatur, nisi prius Præsidentem gratiæ impetrandæ ergo visitaverit.

IV.—Nemo in Sociorum ordinem admittatur, qui medicamentum quodvis arcanum, (nostrum vulgò dictum) in morbis curandis ad quæstum usurpaverit, aut qui Pharmacopœæ aut Obstetricis arte aut mercibus quibusvis vendendis victum quærivaverit, nisi gravi aliquâ de causâ Comitibus Majoribus approbandâ aliter visum fuerit.

V.—Nemo in Sociorum ordinem electus admittatur, nisi prius fidem infra scriptam Præsidenti aut Propræsidenti, coram Sociis præsentibus in Majoribus Comitibus dederit:—"Adniteris pro viribus ut status Collegii perpetuetur, statuta Collegii observabis, aut multas tibi contra facienti irrogandas promptè persolves.

"Secreta Collegii foras non vulgabis.

"Neminem aut in Sociorum aut Candidatorum ordinem cooptandum aut ad medicinæ facultatem in urbe Londino et per septem milliaria in circuitu ejusdem exercendam admittendum, decernes, quem, seposito omni affectu, scientiâ aut moribus minus idoneum esse judicaveris.

“ Omnia denique in arte medicâ pro viribus facies ad honorem Collegii et reipublicæ utilitatem.”

VI.—Quam fidem literis mandatam quilibet Sociis postquam admissus fuerit, insuper confirmet nomine suo subscripto.

FORMA ADMISSIONIS.

VII.—Admittendus flexis genibus manus invicem applicatas humiliter tradat in manus Præsidentis aut Propræsidentis qui dicat :

Ego A. B. Præsidentens vel Propræsidentens hujus Collegii admitto te in Societatem nostram, precorquæ tibi omnia fausta.

VIII.—Omnes Socii tempore admissionis suæ literas habeant sigillo Collegii munitas sub hac formâ.

“ Sciant omnes nos A.B. Medicinæ Doctorem et Presidentum Collegii Medicorum Londinensis, una cum consensu Sociorum ejusdem, auctoritate nobis à Domino Rege et Parlamento concessa, approbasse et in Societatem nostram cooptasse doctum et probum virum T. S. in florentissima Academia Medicinæ Doctorem; largitosque præterea usum et fructum omnium commoditatum, libertatum, ac privilegiorum, quæ Collegio nostros auctoritate prædictâ, et jam concessa sunt, et in futurum concedenda: In cujus rei fidem et testimonium sigillum nostrum commune præsentibus apponi fecimus. Datum Londini in Collegio nostro die Mensis Annoque Domini”

IX.—Si quis postquam in Sociorum ordinem fuerit admissus, Pharmacopœe vel Obstetricis arte, aut mercibus quibuscumque vendendis victum quærivitaverit, statumus et ordinamus illum à Societate nostrâ excidisse.

X.—Si quis Socius criminis alicujus gravioris ac publici damnatus fuerit è Societate nostrâ expellatur si ita visum fuerit majori parti Sociorum in Comitibus Majoribus præsentium, suffragiis per pilas occultè acceptis.

XI.—Si quis Socius medicamentum quodvis arcanum (nostrum vulgò dictum), venditaverit, et delicti hujusce à Præsidente et Censoribus, aut eorum majore parte convictus fuerit; è societate nostrâ, si ita judicatum fuerit à majore parte Sociorum in Comitibus Majoribus, sive Ordinariis, sive Extraordinariis præsentium, suffragiis per pilas occultè acceptis expellatur.

DE PERMISSORUM ELECTIONE EXTRAORDINARIA IN SOCIOS.

I. Quandoquidem fieri potest ut inter Permissos numerentur viri quidam egregii, et de re medicâ præclare meriti, quos statutum nostrum de Sociis in ordinem Sociorum cooptari vetat; statuimus et ordinamus ut non obstante statuto de Sociis, liceat Præsidenti quotannis nec sæpius in Comitibus Minoribus Ordinariis mense Martis habitis, nisi gravi aliquâ de causâ Comitibus Majoribus approbandâ alio mense visum fuerit; unum, pro suo ar-

bitrio, è Permissis qui decennium compleverit à tempore admissionis, utpote morum integritate, doctrinâ et artis medicæ peritiâ insignem, in Socium approbandum Censoribus proponere; qui si Præsidentens et Censores aut eorum major pars, suffragiis per pilas occultè acceptis consenserit, in Comitibus Majoribus Ordinariis postridiè nativitatibus Divi Johannis Baptistæ habitis, à Præsidente in Socium eligendus proponatur; et si major pars Sociorum præsentium suffragiis per pilas occultè acceptis, consenserit, in Societatem nostram quamprimum admittatur.

II. Non licebit Præsidenti alterum iisdem Comitibus Minoribus approbandum proponere, sive vir propositus approbatus fuerit, sive reiectus.

III. Quicumque ita è Permissorum numero in ordinem Sociorum approbandus proponatur, eum approbandum proponat Præsidentens in Comitibus Minoribus hisce verbis:—“ Commendo vobis A. B. qui decennium complevit ex quo tempore in Permissorum-numerum admissus est; quem, propter egregiam morum probitatem, doctrinam, et singularem in arte medicâ peritiâ, omninò dignum censeo, qui, suffragiis vestris prius approbatus, eligendus in Socium proponatur Comitibus Majoribus Ordinariis postridiè nativitatibus Divi Johannis Baptistæ habendis.” Et in Comitibus Majoribus his verbis: “ Propono vobis A. B. propter egregiam morum probitatem, doctrinam, et singularem in arte medicâ peritiâ, in ordinem Sociorum eligendum.”

IV. Non licebit Propræsidenti vel Præsidentis vicario hoc officio fungi.

V. Liceat porro cuilibet Sociorum in Comitibus Majoribus Ordinariis, postridiè Divi Michaelis habendis, aliquem qui annos septem integros in numero Permissorum fuerit, annumque ætatis suæ tricesimum sextum clausit, examinandum proponere.

VI. Nemo verò aliquem è Permissorum numero ita examinandum proponat, nisi prius in Comitibus Majoribus postridiè Divi Johannis Baptistæ proximè habitis suum consilium Collegio palam exposuerit.

VII. Qui Permissum aliquem examinandum proponit his utatur verbis:—“ Liceat mihi proponere Præsidenti et Collegio virum egregium, A. B. qui annum ætatis tricesimum sextum clausit, et qui ultra annos septem Medicinæ facultatem exercuit, ex quo tempore in Permissorum numerum admissus fuit; et quem scio esse aptum habilem et idoneum tam Moribus quam Doctrina, qui in Societatem nostram eligatur.”

VIII. Is adeo, si consenserit major pars Sociorum in illis Comitibus præsentium, juxta formam pro Candidatis usitatam à Præsidente vel Propræsidente et Sociis in tribus Comitibus Majoribus Ordinariis examinatur; et si in singulis examinationibus à majore parte Sociorum præsentium in illis Comitibus approbatus fuerit, suffragiis per pilas occultè acceptis Comitibus Majoribus Ordinariis proximè insequentibus,

à *Præsidente* vel *Propræsidente* proponatur in ordinem Sociorum admittendus; et si consenserit major pars Sociorum in illis Comitibus presentium; suffragiis per pilas occultè acceptis quam primum commode fieri potest, admittatur, dummodo nec lex terræ nec ullum

statutum Collegii nostri eundem ad illud beneficium accipiendum inhabilem reddiderit.

FRANCIS HAWKINS; Registrar.

No. III.—*An Account of the Number of Persons who have been admitted as Licentiates of the Royal College of Physicians of London, from January 1, 1823, to December, 31, 1832.*

Number of persons admitted as Licentiates, from January 1, 1823, to December 31, 1832 } 117.
July 4, 1833.

FRANCIS HAWKINS, Registrar.

In obedience to the order of the House of Commons, the Royal College of Physicians have made the following return, which contains an account of the money which has been received by them from persons admitted as licentiates, from 1st January, 1823 to 31st December 1832; and also an account of the manner in which it has been appropriated. In explanation of this return, from which it appears that the annual expenditure of the

College considerably exceeds its revenue, they beg to state, for the information of the House of Commons, that, in addition to the sums of money mentioned in the following return, the whole income of the College arises from various sources; viz. first, from fees paid by fellows, who each pay on admission 95*l.* 4*s.* a sum including 40*l.* for stamps; secondly, from money paid by extra-licentiates, each of whom pays for letters testimonial, 17*l.* 9*s.*;

and, thirdly, from rents of lands and houses, the donation of former fellows of their society.

But, for the last four years, the whole income of the College has not equalled its expen-

diture; the first amounting to 411*l.* 16*s.* 5*d.*, while its expenditure has amounted to 482*l.* 1*l.* 12*s.* during the same period.

No. IV.—*An Account of the Money which has been received by the Royal College of Physicians from Persons admitted as Licentiates, from Jan. 1, 1823, to Dec. 31, 1832.*

	£	s.	d.	£	s.	d.
One hundred and seventeen persons have been admitted as licentiates, between the 1st January, 1823, and the 31st December 1832, from each of whom has been received 56 <i>l.</i> 17 <i>s.</i> ; the whole amount being	6651	9	0			
Charges immediately connected with the examination and admission of each licentiate; viz.						
Stamps and parchment for diploma	15	0	0			
Fee to president, who attends the three examinations and admissions of each licentiate	2	0	0			
Fee to the four censors for three examinations	4	0	0			
Fee to registrar, who attends and takes minutes of all examinations	1	0	0			
Fee to the treasurer	0	15	0			
Fee to the beadle	1	5	0			
Fee to the porter	0	5	0

THOMAS TURNER, *Treasurer.*

Further, they beg to state, that, with the exception of a lease of the ground upon which the building now stands, the College has never received any pecuniary aid from the Crown since its foundation. The original building for the meetings of the corporation was purchased, and added to, by the private subscriptions of the fellows of that time; and when this was burnt down at the great fire of London, the edifice in Warwick-lane was built at the cost of the fellows; and the funds for the erection of the present building in Pall-Mall East, which cost 25,000*l.*, were raised from the sale of the premises in Warwick-lane, which yielded 9000*l.*, from 2000*l.* given by the trustees of Dr. Radcliffe, and from the subscriptions of the present fellows.

To meet these great demands, the College has foregone every expense, except such as was absolutely necessary to promote the legitimate objects of its institution, to further which the fellows still continue a small annual subscription.

WRIGHT ON CARDIAC PATHOLOGY.

Carditis and Pericarditis—lymphatic or membranous.

THE high degree of sensibility attributed to the textures of the heart, and the immense importance of the function performed by that organ, seem calculated to render it peculiarly incapable of enduring irritation, or undergoing morbid changes, without betraying manifest and formidable signs of the disturbance it suffers, or the lesion to which it has been subjected.

But whatever may have once been thought of the liability to instant and urgent danger from diseased actions accruing to the heart's substance, it is now very well known that morbid states of this part are by no means rare, and also that imminent or immediate danger is not the invariable attendant on cardiac affections. It is also sufficiently ascertained that diseased conditions of the heart may arise, continue long, and effect great changes in the texture, connexions, &c., of that organ, without any certain or violent display of suffering or danger. The affections of the heart and its appendages, denoted by the terms prefixed to these remarks, have often been found (by after search) to have constituted the occasion of many symp-

toms, which, during life, were either deemed of little importance, or too equivocal and obscure to allow of their being referred to so serious a cause as disease of the heart itself. Carditis and pericarditis, singly or together, have progressed in a silent and undistinguished manner, to the extent of almost total alteration of the natural condition and relations of these textures to each other, and to other parts, and there has been nothing to mark the change that was going on, or to reveal the special seat and nature of such disease or degeneration.

If any proof was wanted to show the fallacy of former opinion respecting the incapacity of the heart to bear direct irritation without obvious derangement of its common office, and great, or even fatal disturbance of its extensive and important physiological associations, such requirement is amply supplied by autopsic evidences. The strong vestiges frequently met with on the dissecting table, of ancient inflammation and its consequences, about the heart and its appendages, furnish unequivocal testimony on this head, and go to show plainly, that the heart, like many other fibrous structures, may endure the gradations of acute and chronic inflammation, not only with safety to life, but in a manner little obvious, and not easily discriminated. The records of surgery, of military surgery especially, supply full confirmation of the same fact, in the numerous instances reported, where the heart has been found to have suffered former violence (to the extent of actual lesion), of which the traces and the proof were still palpably betrayed. That the attributes of intrinsic sensitiveness, proper to this important organ, have also been greatly overrated, may in like manner be inferred, on the testimony of the facts and circumstances already noticed, which appear calculated to discountenance the presumption of any peculiar or exquisite organic sensibility in parts capable of undergoing irritation and its consequences to the extent pointed out, without those attendant symptoms

—pain, disordered action, &c., which might clearly indicate the place, degree, or duration of morbid influence, suffering, and change. Even direct evidence to the same effect would seem to be furnished by some experiments, performed in a spirit at least sufficiently adventurous, and affording results highly curious, though of small apparent utility. While acupuncture was in fashion for the cure of rheumatism, the needle (we are told) has been passed toward the heart, for supposed rheumatic neuralgia of that seat, until its succession of action and repose was plainly represented by the alternate rise and fall of the instrument, and yet no expression of particular pain or distress was extorted by this (as it would seem) actual penetration of the substance of the organ.—*American Journal of Med. Science*, May, 1833.

REFORM IN MEDICAL CORPORATIONS.

COLLEGE OF PHYSICIANS (*London*).

Copy ordered—"Of all the regulations and by-laws of the College of Physicians of London, under which Doctors in Physic have been admitted Licentiates and Extra Licentiates of the College since the year 1771."

"Accounts of the number of persons who have been admitted Licentiates and Extra Licentiates of the College of Physicians of London, in each year from 1st January 1771 to 31st December 1832."

"Of all the money which has been received by the College of Physicians from the persons admitted as Licentiates and Extra Licentiates, from 1st January 1771 to 31st December 1832; stating the charge from each person for admission, and the aggregate amount received from each class, and the manner in which the several sums have been applied."

"Of the number of persons who have been prosecuted by order of the College of Physicians for mal-practice, or for refusing to apply for their licence to practise medicine, in each year since 1st January 1771; stating

for what offence they were proceeded against, the dates of the order for each prosecution, the result of it, and the expenses paid by the College on each suit."

"Return of all bequests to the College; their nature and amount, when left and when received; the names of those who made the bequests, stating whether they were Fellows, Licentiates, or others; and also, the manner in which each bequest has been applied by the College."

MEDICAL CORPORATIONS (*Scotland*).

Address for—"1. *Edinburgh*.—Copies of all the Regulations and By-laws under which Graduates in Physic have been admitted Fellows of the Royal College of Physicians of Edinburgh, since 1st January 1771 to 31st December 1832;—2. Of the Regulations and By-laws under which medical practitioners have been admitted as Fellows and Licentiates of the Royal College of Surgeons of Edinburgh, since 1st January 1771 to 31st December 1832."

"*Glasgow*.—Copy of all the Regulations and By-laws under which physicians and surgeons have been admitted members, or by any other title of the Faculty of Physicians and Surgeons of Glasgow;—2. Also, the number of persons who have been prosecuted by order of the College of Physicians and Surgeons of Edinburgh and Glasgow, for mal-practice, or for refusing to apply for their licence to practise, in each year, since 1st Jan. 1771."

MEDICAL CORPORATIONS (*Ireland*).

Address for—"1. Copy of all the Regulations and By-laws under which Graduates in Physic have been admitted Fellows of the Royal College of Physicians of Dublin, since 1st January 1771 to 31st December 1832; 2. Also, Copy of the Regulations and By-laws for the admission of Licentiates during that period;—3. Copy of all the Regulations and By-laws under which medical practitioners have been admitted as Surgeons of

the Royal College of Surgeons of Dublin, from 1st January 1771 to 31st December 1832;—4. Copy of the Regulations and By-laws under which medical practitioners have been admitted as Apothecaries of the Company of Apothecaries of Dublin, since

their first establishment to 31st Dec., 1832;—5. List of all persons prosecuted by order of the College of Physicians and of Surgeons, and by the Company of Apothecaries, in Dublin, for mal-practice, or for refusing to apply for a licence, since 1771.”

ACCOUNT OF ALL MONEY RECEIVED FOR DIPLOMAS BY ROYAL COLLEGES OF SURGEONS IN LONDON, DUBLIN, AND EDINBURGH.

No. I.—ROYAL COLLEGE OF SURGEONS IN LONDON.

An Account of the money which has been received by the Royal College of Surgeons in London, for diplomas granted to persons who have been examined from 1st January, 1823, to 31st December, 1832, and of the manner in which it has been appropriated.

In the year 1823, the sum of £6,088 19s. was received by the College for Diplomas, and appropriated as follows:—Five guineas for each diploma to the Court of Examiners, consisting of ten members, making together the sum of £1,548 15s. and the remaining sum of £4,540 4s. was added to the funds, and applied for the general purposes of the College.

17th July, 1833.

BY ORDER,

EDMUND BELFOUR, *Secretary.*

No. II.—ROYAL COLLEGE OF SURGEONS IN DUBLIN.

Letter from J. Kerin, Esq. to S. M. Phillipps, Esq., Whitehall.

1st July, 1833.

SIR,—In compliance with the desire of Viscount Melbourne, conveyed in your letter of the 26th ultimo, I have the honour to transmit an “Account of the money which has been received by the Royal College of Surgeons of Dublin, for diplomas granted to persons who have been examined from 1st January, 1823, to 31st December, 1832, and of the manner in which it has been appropriated.”

As it is the wish of the college to

afford the fullest and most satisfactory information respecting the amount and application of its funds, I have to state that the sum returned as having been paid for diplomas, is not the only sum received from, or on account of, persons receiving such diplomas, but that each pupil, upon being bound apprentice to a member or licentiate of the college to qualify him to obtain such diploma, pays a registry fee of ten guineas, and the member or licentiate, to whom he is indented,

also pays to the funds of the college a similar fee of ten guineas.

I have further to inform you, that licentiatees of the college upon becoming members, and thus acquiring corporate rights, are required to pay a fee of thirty guineas. I have, therefore, drawn up a second return for the use of the House of Commons, should they think such necessary.

I have the honour to be,

Sir,

Your most obedient humble servant,

J. KERIN, *President.*

An account of the money which has been received by the Royal College of Surgeons in Ireland, for diplomas granted to persons who have been examined from 1st January, 1823, to 31st December, 1832, and of the manner in which it has been appropriated.

—£7500.—

The above mentioned sum has been exclusively appropriated to the following purposes:—

The erection, preservation, and repairs of the buildings of the college; the formation, augmentation, and preservation of the museums; the purchase of books for the library; and the payment of wages to servants, and salaries and gratuities to the housekeeper, registrar, and curator of the museum.

The members of the college perform the various duties of president, examiners, secretary, &c. without fee or reward; and it is to be observed, that since the foundation of the college, no member has received any portion of the funds of the college for such services, except the late Mr. Henthorn, who received an occasional remuneration to the amount of about 600*l.* for his services as secretary during a period of fifty years.

JAMES KERIN, *President.*

Royal College of Surgeons in Ireland, 1st July, 1833.

An account of the money which has been received by the Royal College of Surgeons in Ireland, from 1st January, 1823, to 31st December, 1832; distinguishing the amount which has been received for registry of pupils, for diplomas, and from Licentiatees on being elected Members of the College, and of the manner in which the same has been appropriated.

Amount of Fees for Registry of Pupils.	Amount for Diplomas.	Amount received from Licentiatees on being elected Members.	Total.
£ 11,400	£ 7,500	£ 1,150	£ 20,050

The above mentioned sum of 20,050*l.* has been exclusively appropriated to the following purposes:—

The erection, preservation, and repairs of the buildings of the college; the formation, augmentation, and preservation of the museum; the purchase of books for the library; and the payment of wages to servants, and salaries and gratuities to the housekeeper, registrar, and curator of the museum.

The members of the college perform the various duties of president, examiners, secretary, &c. without fee or reward; and it is to be observed, that since the foundation of the college, no member has received any portion of the funds of the college for such services, except the late Mr. Henthorn, who received an occasional remuneration to the amount of about 600*l.* for his services as secretary during a period of fifty years.

JAMES KERIN, *President.*

Royal College of Surgeons in Ireland, 1st July, 1833.

No. III.—ROYAL COLLEGE OF SURGEONS IN EDINBURGH.

*Letter from J. Campbell, Esq. to S. M. Phillipps, Esq. Whitehall.**Edinburgh, 5th July, 1833.*

SIR,—In compliance with the instructions contained in your letter of the 26th June, I have now the honour to transmit an account of the money which has been received by the Royal College of Surgeons of Edinburgh, for diplomas granted to persons who have been examined, for a period of ten years, commencing in 1822, for the purpose of the same being laid before the House of Commons.

In consequence of the accounts of the Royal College having always been made out from Lammas to Lammas, it has been found necessary to frame the accompanying return from that

term, and not from the 1st of January, according to the order contained in your letter, as it would otherwise have been nearly impossible to have given the exact number of diplomas, and the fees arising from them, with the necessary degree of accuracy, according to the manner required; but I trust that this slight deviation from the desire of the House of Commons will not prove of any material importance.

I have the honour to be, Sir,

Your obedient servant,

JOHN CAMPBELL

President Royal College of Surgeons, Edinb'

Account of the money which has been received by the Royal College of Surgeons of Edinburgh, for diplomas granted to the persons who have been examined from 1st August, 1822, to 1st August, 1832, and of the manner in which it has been appropriated.

The sums received for diplomas are paid into the general fund of the College and expended with it, so that it would be difficult to distinguish precisely the particular purposes to which they have been applied. The College have thought it right, therefore, to subjoin the following statement of their whole funds and expenditure, by which it will appear that not only the whole sums received for diplomas, but the part of their other funds remaining

after the payment to the Widows' Fund, and defraying the ordinary expenses of the College, have been expended for public and scientific purposes; more especially for the purchase, collection, and exhibition of an Anatomical and Pathological Museum, which is open for the use of the members and students of the medical profession and the inspection of the public.

Account of the funds, income, and expenditure of the Royal College of Surgeons of Edinburgh, during the period of ten years, from Lammas 1822 to Lammas 1832.

The INCOME of the College consists of the dues of diplomas, the entry money of Fellows, fees of indentures of apprentices, fees of certificates for navy surgeons, and fees of registration of students.				
	£	s.	d.	£ s. d.
From these sources there had been accumulated at Lammas 1822 the sum of	10,033	0	9	
And the value of the old Hall and feu duties connected with it	2,100	0	0	12,133 0 9
Received since Lammas 1822 to Lammas 1833, (being ten years,) viz.

The above property has since been sold for the said sum of 2,100 <i>l.</i> and the proceeds applied to the reduction of the Debt.				

MEETING OF THE PROFESSION AT TIPPERARY.

THE spirit of reform is abroad in all grades of the profession ; meetings for the purpose of petitioning parliament to remove the heavy grievances under which the profession labour are being held in various parts of the empire ; and rejoiced are we to add, that the pervading feeling at these meetings is as averse to the mock agitation recommended by one of our contemporaries, as it is opposed to the senseless shallow system of reform supported by the other. In the *Tipperary Free Press* is a notice of a meeting of the medical practitioners of that county, at which the following spirited resolutions were passed unanimously :—

Resolved—“ That the monopoly enjoyed by the medical and surgical graduates of the King's and Queen's College of Physicians and of the Royal College of Surgeons in Dublin in their exclusive eligibility to the situation of medical attendants to County Infirmarys in Ireland, is unjust and highly injurious to the members of the British Colleges.”

Resolved—“ That we petition the Legislature, praying for a parliamentary inquiry into the general state of the medical profession in these islands, and that the graduates of the British universities and Colleges be placed on the same footing in *Ireland* as in *Great Britain*.”

We most cordially agree with the liberal feelings which these resolutions display ; but we doubt much the propriety of petitioning Parliament at this late period of the session. Rather let the supporters of this meeting labour in the good work of reform during the ensuing recess, and when Parliament again re-assembles, let them present a firm but respectful petition to the Lords and Commons, praying them to remove, as speedily as the labours of the commissioners will permit, those unjust and heavy grievances under which the members of the London College of Surgeons, at present prac-

tising in Ireland, labour. We need scarcely add, that our pages are always open to any communications in aid of this good cause.

LONDON MEDICAL ASSOCIATION.

A SUNDAY paper (the *Spectator*,) in an article on this subject makes the following remark, in the support of which we join :—

“ The object of the Association being to throw a strong and clear light upon the hitherto occult subject of medical reform, we would suggest, that, in addition to the publication of the successful essays, a tabular synopsis of the various plans proposed by the unsuccessful candidates should be prepared, with a brief running commentary on each of the principal points of detail, by the adjudicators of the prizes. The defects of a bad plan would thus be converted into the tests of a good one.”

We recommend the above to Dr. Epps's notice.

PRIZE ESSAYS OFFERED BY THE ROYAL COLLEGE OF SURGEONS IN LONDON.

FOR 1833—“ Formation, Constitution, and Extraction of Urinary Calculi.”

FOR 1834—“ Injuries and Diseases of the Nose and the Nasal Sinuses, and Tetanus.”

Essays to be delivered before Christmas in each year.

STRYCHNINE IN CHOLERA.

WE have employed strychnine, as recommended by Mr. Jenkins, in three cases of malignant cholera, with success. It rouses the nervous energy astonishingly, and checks the most violent diarrhoea. One gentleman who had diarrhoea for a week was relieved by six of the pills. We strongly advise our readers to try this medicine.

THE
London Medical & Surgical Journal
 Saturday, August 17, 1833.

PREVALENCE OF MALIGNANT
 CHOLERA.

It appears, by a statement in the *Caledonian Mercury*, that the inhabitants of Edinburgh have been taxed to the amount of £11,457 2s. 5½d. for 1886 cases of cholera, being upwards of £6 a head for each patient, or more than *seven times* the sum which was required for each patient in Glasgow, the number of cholera patients there having been 4290—the expense £3726 11s. 9d. It is also stated, that there is a mistake of £100 in the “summation”—“an error, however, which is not in favour of the public.” The enlightened people of Edinburgh are tolerably well fleeced by their renowned Board of Health—a cringing, crouching junta, of the same stamp as our ever-to-be-lauded worthies of Whitehall-place. We wish that the intrepid and honest exposé of public knavery, Mr. Hume, would move for an account of the expenses incurred by the unprincipled set of men who formed the Boards of Health in London—men who drove the country and the greater part of the world, mad, by their ignorant and selfish proclamations; and who, when the cholera had ceased, unanimously agreed that it was *not* contagious, and that cholera patients might be taken into the Metropolitan hospitals! The delinquencies of these persons, and their servile imitators in Edinburgh, have excited the contempt

of every member of the profession who has the slightest pretensions to medical erudition or science. We alone advocated the non-contagiousness of cholera; not a journalist—not a physician in this metropolis, had the courage to join us against the ignorant conclusion of the first and second Boards of Health. Our enlightened and honest French contemporaries joined us, the profession in general followed, and finally the degraded men themselves who had perpetrated the greatest inhumanity upon record.

The public press saw the justice of our conclusions, and ran down the harpies that preyed upon the credulous and greatest part of mankind. The same disease is now, we grieve to state, as prevalent as it was last year, but in a modified form; and why, we boldly ask, does not the government appoint a Central Board of Health? We answer, simply because the eyes of the government, of the country, and of the world have been opened by the gross misconduct, profound ignorance, and self-interested policy of the London and other Boards of Health. We give the government credit for this discrimination, though it alone is responsible for all the mischief done by the former Boards of Health, for having appointed men totally incompetent to discharge the important duties of controlling the commerce of this great country, and of deciding the nature of an epidemic, which most of them had never seen, and two only of whom, (one of them famed for making every thing contagious,) had seen at

all. Nevertheless, the Board so constituted paralysed and stupified the minds of all the hospital physicians of London to such a degree, that the gates of our great hospitals were closed against the unhappy victims of cholera. That the hospital physicians should sanction this inhuman proceeding was to be expected, because they are nearly all Fellows of the College, monopolists who dare not but bow their heads to their lords and masters who formed the first Board of Health, and having once committed the egregious folly of refusing admission to cholera patients, they could not act differently, as the second, or central mischievous Board, followed in the wake of its predecessor.

When the disease broke out subsequently in Paris, the whole of the physicians and surgeons of that capital, with one or two dissentients, unanimously declared the disease to be non-contagious, and that quarantine was *absurd*. This country is now actuated by the same conclusion,—there is no quarantine,—there are no dragoons to surround the infected districts, as once sagaciously suggested by the first Board of Health. Our readers are well aware of our advocacy of the non-contagiousness of cholera from its first appearance in this country, and we have now the gratification, the glorious triumph of having the medical world of our opinion. Had the contagionists of this kingdom been acquainted with the history and progress of former epidemics,—had they reasoned logically

or philosophically,—had they candidly admitted the incontrovertible facts submitted by the laborious and honest Hamett and a host of others, they never could have pronounced that malignant cholera was a contagious disease, or proclaim such unscientific nonsense, as “a contingent contagion.” We should like to know what contingencies will produce syphilis, gonorrhœa, small-pox, measles, scarlatina, or vaccina, besides their respective poisons. It will be a singular fact in the medical history of this kingdom, that the disease which was officially declared to be contagious in 1832, was pronounced to be non-contagious after its disappearance in the same year, (see the resolutions of the Central Board of Health in No. 46 of this Journal), and in the year following, 1833, when it reappeared, nothing was done by the government to arrest its progress, and nobody believed it to be contagious. If this be not the pitchpipe of discord, the disagreement of doctors, we know not what is. We hope better things in future, when the Colleges of Physicians in the United Kingdom will be filled by men of science, of erudition, and experience, who are now excluded, and not as heretofore and at present, by individuals of a very different character, who for centuries have shed their baneful influence over the cultivators of medicine, and society at large.

CHOLERA is abroad again—so say the daily journals, and so says the

practice of every medical man in London; yet, we are very happy to add, that its virulence is not of that fierce and fatal nature which caused the deaths of so many in its progress through the country last year. From the severe experience of the total inefficacy of the Board of Health, which Government have learnt, we hope to be spared the necessity of pointing out again the complete incapacity of all such commissions to perform the duties assigned to them.

A certain witless contemporary, with a view we suppose of "taking time by the forelock," was hoaxed into publishing some *soi-disant* arrangements of Government relative to the cholera; and being anxious to hoax the public in return, the Editor furnished a slip of "The Cholera Arrangements" to a morning paper. This was hoax upon hoax—but the parties were so blind they could not see it.

A CASE OF DOUBTFUL PREGNANCY.

BY M. L. MASON, ESQ. M.R.C.S., S.A.

A. B., ætat. 20, extremely hysterical, supposed herself pregnant of her first child in October last, after which time she experienced a variety of unusual sensations; the areola round the nipple became darker, she complained of sickness of stomach every evening, a symptom she always experienced *post coitum*. About the fourth month and a half she quickened and menstruated; she expected to be delivered about the end of July. Early in this month she fell, and from the moment of the accident never felt the motion of the child; the breasts became softer, and the weight in the abdomen became much lower. On Thursday, the first of

August, she walked a short distance, and on her return homewards, experienced pains about the back and loins, for the alleviation of which she took some gin and water, and in a short time after its ingestion, discharged about a pint of fluid per vaginam. Her pains recurred at first every quarter of an hour, and soon every five minutes, but the os uteri felt natural, and the cervix was in its normal condition. The pains recurred with great severity until twelve o'clock on the following Saturday, when it was concluded that she was not pregnant, and that her disease was tympanitis. She was ordered draughts, composed of mist. camph., with double the quantity of camphor sp. am. arom., liq. opii. sed., olei menth. pip., every hour, and an opiate liniment to the abdomen. She vomited the first draught but retained the second, after which she expelled a good deal of gas, and slept six hours. On Sunday there was scarcely any pain, and none on Wednesday. The abdomen had very much diminished. She complained of soreness in the region of the right kidney, which had been present since October, and on this region being pressed, it excited the pains already mentioned. Six ounces of blood were removed by cupping, the size of the abdomen rapidly diminished, and on Thursday there was no tumefaction whatever.

Reviews.

A Treatise on those Disorders of the Brain and Nervous System usually called Mental. By DAVID UWINS, M.D. 8vo. pp. 235. Renshaw and Rush.

If we are to judge of the spread and rapidity of a disease by the numerous works written for its elucidation, insanity must have increased rapidly of late years. Volume after volume has been written and published until in-

sanity has become a "household word" among us, and we have been rendered familiar with its every delusion. Yet the disease still preys on, mind after mind falls powerless beneath its fearful grasp, and its cure or prevention seems "a mystery" still. But few works have treated in a familiar manner upon this disease—few authors have been bold and energetic enough to speak of so fatal a malady to the public; and as long as medical men and authors envelope the symptoms and treatment of this disease in mystery, so long will it remain so.

Dr. Uwins' pamphlet on Insanity (published a short time since) prepared us for the perusal of the work before us, which, we are happy to find, treats the subject in a happier and more fluent style than has yet been done by any author that we are aware of. His extensive experience in every grade of those "Diseases usually called Mental," has been surpassed by no physician of the present day. His views of these affections are therefore founded on juster and truer principles; his ideas are enlarged and liberal, and the "whole tenour" of the volume bespeaks a mind whose perceptions of disease are based on the most extensive daily experience. We quote the following passage on the "Sources of Insanity:"

"In this life there is no unmixed good. What are considered improvements in our nature and social habits are necessarily accompanied by corresponding impediments to their being received as actual advancements in true felicity, the object aimed at in all our institutions and arrangements.

"That the sources and resources of refinement are, in a great measure, the sources of insanity, all theory and observation attest. Savages and children have intense feelings; they are actuated by mistaken motives, and pursue ruinous projects, and therefore may, in one sense, be deemed the subjects of madness; but wanting the complication of being, which social existence implies, there is not that

mischievous admixture of motive and counter-motive—not that restlessness in purpose and project—not that ambitious anticipation of prospective good, which, like the horizon, continues still at the same distance from the pursuer;—and, more than all, there is not that debility and deterioration of nervous energy which leads to lunacy, as bodies tend to the earth, and water seeks its level.

"It is, however, remarkable, that those are greatly obnoxious to mental aberration whom refinement would scarcely seem to reach. The poor are certainly more liable to mental alienation than would *à priori* be supposed; but, besides that, we have a fruitful cause of insanity among the lower classes immediately to be adverted to; the fact is partly attributable to the circumstance of their being in some measure within the reach of the evil without the benefit of counteractives.

"Although 'the cook-maid grows nervous and quotes Abernethy,' she is obliged to pursue her calling despite of her sensitive organisation; and these kitchen refinements bring with them moreover disrelish and discontent of particular modes of life. Nervousness and dyspepsia are thus increased by mental causes, and the borders of actual insanity are trodden upon by individuals, who ought not to be sensible that they have a stomach to be pampered, or nerves to be irritated.

"It is a curious fact, and it being mentioned here may serve to strengthen my assumption, that the multiplication of rules about diet and regimen, brings with it an increase of the very evil that is so anxiously sought to be avoided. That thus the most sensitive parts of our bodies should become especially affected by refinement being pushed on too rapidly, or in a wrong direction, is in the due order of things; and it behoves the guardians of physical and moral health to look well to their doings, and to be assiduously careful that their interference may not do harm as well as good."—pp. 48—52.

In this manner are the subjects of religion, love, spirit drinking, opium eating, atmospheric changes, &c. considered as fruitful sources of insanity; and all, who have had insane patients under their care, will agree with the author on these points. On the debateable question of whether a lunatic shall be confined or coerced, our author makes the following appropriate remarks:—

“There is a vast number of cases in which the question of custody or control must be considered absolutely relative; a total idiot, either from birth or accident, an imbecile from apoplexy, a confirmed melancholic, may all be fit subjects for a lunatic asylum, but if relations choose to take the responsibility of their management, and the trouble of it into the bargain, it is not the business of others to interfere, provided cruelty or gross mismanagement be not exercised. There are many instances of intellect having been broken down by age or by apoplexy, and where the persons thus attacked are rendered totally incapable of pursuing the ordinary duties of life.

“There is another difficulty which often presents itself in reference to the absolute justice of confinement, and which must in some measure be left open to the decision of good sense and right feeling, beyond the authority of presumptive will. I allude to those cases which while they are in asylum custody do not exhibit the smallest characters of alienated intellect, but become wild and ungovernable immediately they are set at large.”—pp. 129—132.

The chapter on “The Moral Management of Nervous Disorders” and “The Medical Treatment of the Insane,” will well repay the reader’s perusal. We regret that our space will not allow us to notice them at greater length. The work is one of great practical experience, and will do more for the benefit of mental diseases than any former one published on the subject.

A Treatise on Diseases of the Eye.
By W. LAWRENCE, F.R.S., Surgeon to St. Bartholomew’s Hospital, and Lecturer on Surgery at that Hospital; Surgeon to the Bethlem and Bridewell Hospitals, and late Surgeon to the London Ophthalmic Infirmary: 8vo. pp. 730. London, 1833: John Churchill.

THE basis of the work before us consists of the lectures on the diseases of the eye, delivered by the distinguished author at the London Ophthalmic Infirmary; but the subjects are now considered in greater detail, the opinions and experience of others are quoted and examined, and cases are introduced for practical illustration, wherever it could be done with advantage. We have compared this treatise with the original lectures, published by our contemporary, the *Lancet*, and also with the translation of them into French, by the late M. Billard d’Angers, and we find that Mr. Lawrence has added all the facts that have been published since he delivered his lectures in 1825-26. This work forms therefore an excellent treatise on the eye, and is one of the ablest that modern times have produced. It is replete with the most valuable information on the important subjects of which it treats; accumulated from the most extensive observation and experience, and from all the standard writers, domestic and foreign, upon the numerous diseases of the organ of vision. The author has evinced great research, observation, and talent in arranging his treatise. He has quoted very largely from the works of national and foreign writers, —British, Irish, German, French, and Italian. The nature of the work precludes us from attempting to analyse it. We express our opinion of it by stating, that so far as it extends, it is a work of reference and standard authority. It contains information omitted in Mr. Mackenzie’s treatise; but this latter contains a vast deal omitted by Mr. Lawrence. Neither of these admirable works supersedes the other,

and both are necessary for the study of ophthalmic diseases. They form the best and most complete system of ophthalmography extant;—they reflect the greatest credit upon their authors, and are most valuable additions to British surgery. Every medical practitioner, who is anxious to pursue his calling with credit to himself and benefit to his patients, will possess both works. The treatises of Lawrence and Mackenzie are twin brothers, inseparably united, and richly deserving of the patronage of all the professors of the healing art in these and other civilised countries. After the expression of this opinion, it is scarcely necessary for us to state, that we strenuously recommend this work to our readers.

Cyclopædia of Practical Medicine.
Part XVII.

If there have been few works in the present day whose pretensions have been greater, or whose contributors have ranked higher in the profession than those whose names appear in this Cyclopædia, so have there been few to whom "a name and nothing more" could have been with such justice or propriety applied. The very title of the work is a misnomer; for, of the hundred and one "Practical" Articles in it, ninety and nine are "theoretical," and nothing more; and this may be plainly proved by referring to different articles by the same authors in other works of the day, and comparing them with the contents of the Cyclopædia. That the profession at large, with the exception of the writers and their immediate friends, are abundantly disappointed with the work is plain, from its being now published only on *alternate months*.

From the high-sounding names attached to the work, we were inclined to hope that the numbers would have improved in character and contents as the work proceeded; but, so far from this, the seventeenth number now before us contains only six articles, written in a dry verbose style,

and affording us little or no new information upon the subjects treated of,—pneumonia and pneumo-thorax may be placed by the same articles in Thomas's Practice of Physic.

Dr. Montgomery's article on "The Signs and Diseases of Pregnancy," although requiring much condensation, yet contains more original and valuable matter than either of the subjects preceding it.

The work will now be completed in three numbers, which, for the character of the editors and contributors, will, we hope, be an improvement on those preceding them. We shall give them our candid and honest criticism, which, though not, perhaps, valued so highly as that of our fellow journalists, will not be the less true because the less redolent of praise.

—
French Medicine.

Bloody Tumour, simulating Encephalocele.

A CHILD, a month old, had a small oval tumour, situated over the posterior fontanelle of the right side. When first seen by the medical attendant, it had attained the size of a small hen's egg; in structure it was soft and slightly resisting; slight pressure upon it diminished its volume, and its pulsations were synchronous with those of the pulse. Stupor came on if pressure over it was long—continued; gentle and gradual compression was ordered to be used, and at the end of three weeks the tumour, though not diminished in size, was more diffused under the scalp, and pressure over it no longer caused stupor. In the course of a few days repeated bleedings from the nose and mouth came on, and in a short time the tumour entirely disappeared.—*Gaz. Méd.*

Endermic treatment.

An ointment made of equal parts of lard and liquor ammon. fort. is first applied to the skin, and the application repeated every five minutes, until

the vesication is effected. The cuticle is then removed and the medicine laid on the abraded surface. It is stated that half a grain of acetate of morphia applied to a blistered surface, near the origin of the sciatic nerve, has, in twenty-four hours, cured a severe neuralgia of the leg; and that sulphate of quinine, when it could not be administered internally, has, by being used in this way, speedily put a stop to a fit of ague.—*Annal. de la Med. Phys.*

Sigaullian operation.

M. Baudeloque, the nephew, states, that he has just performed this operation on a pregnant woman, according to his own method, with success. The child was born alive, and the mother, who herself nursed it, has not experienced any of those unpleasant consequences which commonly follow the section of the symphysis pubis.—*Revue Médicale.*

German Medicine.

Preventive of Cholera.

Sulphate of quinine is strongly recommended as a prophylactic of cholera. It has been given, it seems, to a great number of poor and weakly people, in the dose of two to four grains twice or thrice a-day, with unparalleled success. It may either be administered separately or made into pills, with cajeput oil and extract of liquorice.—*Gräfe und Wallher, Jour. der Chir.*

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Fungus Hæmatodes of the Knee Joint.

JOHN MASON, a strong and athletic man, ætat. 35, was admitted into the hospital on the 31st July, under the care of Mr. Hawkins, for fungus hæmatodes of the knee. The history of his case is as follows:—Several months ago, a small colourless tumour,

unattended by pain, appeared on his knee, immediately over the patella. At first he suffered no inconvenience, but by degrees a very painful and acute sensation darted through it, and ultimately became frequent. The surface of the tumour remained for some time even and smooth, but irregular projections were soon discovered, and the tegumentary coverings assumed a livid red colour. Several openings formed on the tumour, through which a thin foetid sanguineous fluid was discharged. The tumour at length burst, and a fungus of small dimensions presented itself; and rapidly increased in size. It was characterised by a constant tendency to bleed. The patient being much distressed and inconvenienced by the pain, applied for admission into the hospital on the 31st July.

On examination, the fungus imparted a sense of fluctuation, was much ulcerated, and presented a ragged, brownish surface; the skin round it was dense and shining; the fungus itself was of a dark red colour, easily torn, and bleeding on the least friction. The absorbent glands in the vicinity of the disease were affected; and had become somewhat enlarged.

Aug. 7. Patient suffers considerable pain; has not slept last night; appetite bad; bowels sluggish; pulse 86. Strong cathartics were administered; and to alleviate the pain anodynes were also given.

Mr. Hawkins, having given up all hopes of saving the limb, and being aware that an operation could only be successful when performed in time, proposed amputation of the limb, to which the patient consented. It was accordingly done on Thursday, August 8, a few inches above the knee-joint.

Examination of the Fungous Tumour.—On Friday an examination of the amputated limb took place in the operating theatre, under the inspection of Messrs. Hawkins and Babington. The limb was injected by Mr. Johnston, one of the dressers of the hospital.

Mr. Hawkins having made a longitudinal section of part of the femur, patella, and tibia, laid open the seat of the disease. On examination, it appeared that an intimate connexion existed between the fungus and the patella, and not between it and the lower end of the femur, as had been anticipated; the tibia on being cut through appeared highly vascular; the muscles round the fungus had entirely lost their fibrous or proper character, and were of a pale colour, very soft, and yielding to the least touch of the knife. The fungus itself was found to consist of a very soft cerebriform substance, with thin membranous septa intersecting it. An immense number of cysts were discovered in the substance of the fungus, which contained a portion of coagulum. It also exhibited a structure medullary in its nature, and several lobes of various colours were scattered through it.

A section of the fungus was immersed in spirits, and will be preserved among the collection of morbid preparations in the Anatomical Museum of the Hospital.

Monday, Aug. 12. Patient feels rather feverish; appetite tolerably good; pulse soft and compressible; sleeps well, and enjoys good spirits; bowels regular; looks cheerful.

Hæm. salin. ʒiiss.

Vin. antim. ℥i. xij.

Let him take the draught every six hours.

Wednesday, Aug. 14. Patient going on well; bowels very regular.

Inguinal Hernia unexpectedly reduced without Operation.

John Thompson, a very miserable looking and emaciated man, ætat. 55, was conveyed to St. George's Hospital at 10 o'clock on Saturday night, Aug. 10th, under the following circumstances:—

He had been in the hospital two years ago for inguinal hernia, under the care of Mr. Hawkins. At that time he became furiously delirious. The hernia was then completely reduced by Mr. H., and the patient

was discharged, with a truss, which he has worn ever since. He was in the habit of taking off the truss every night on going to bed. On Saturday evening last, about nine o'clock, he removed it on going to bed, when the intestine suddenly slipped down, and, notwithstanding his most unremitting efforts at reduction, could not be returned. He was accordingly conveyed to the hospital immediately.

On his admission his pulse was at 90; copious perspiration; and he was evidently suffering great agony. Every exertion was made by the house surgeon to reduce the hernia, but without effect. The tumour extended from the abdominal ring into the scrotum about four inches. The patient complained of a very violent pain in the epigastric region, which was attended with frequent vomiting. Had a great desire to pass feces, but was unable to do so. The tumour felt hard.

After several ineffectual attempts to reduce the hernia, an enema was given, and the patient was put to bed.

Sunday, Aug. 11. The patient has spent a restless night; vomiting still continues; but not stercoraceous. Several efforts were made this day at reduction, but they were all ineffectual. The taxis was resorted to in vain. The patient has had one slight fecal discharge.

On Monday the patient was put into a warm bath, and kept in warm water of the temperature of 108°, till syncope supervened. Assiduous exertions were made at reduction while the patient was in the bath, but all proved futile.

About one o'clock Mr. Keate, for the first time, saw the patient, and endeavoured to reduce the hernia, but was as unsuccessful as the house surgeons had been. There now appeared to be no alternative but an operation, which was immediately proposed by Mr. Keate, with the patient's consent. All the preparations for the operation being made, Mr. Keate was in the act of proceeding to the operating theatre, when Mr.

Hawkins, who had been trying the reduction for a long time, succeeded in returning back the intestine. On Mr. Keate's return to his patient he found the hernia completely reduced. The operation was of course abandoned.

In the evening an enema was given, which brought away a small fecal evacuation.

Tuesday, Aug. 13.—Bowels very inactive.

Mag. sulph. ʒj,
— *carb.* ʒj,
Tinct. opti. mvi,
Aqua menth. pip. ʒss.

Let him take the draught every six hours.

Wednesday, Aug. 14.—No evacuation since yesterday morning; repeated vomitings of green bilious matter; the intestine still remains up; the abdomen is less tense and painful; he looks better, and slept well last night.

Oleum ricini, ʒj, *statim*.

Discontinue the draught.

Fracture of the Clavicle.

Martha Toogood, whose case we gave last week, (fracture of the clavicle,) is going on very well. Mr. Babington has put a thick padding under the axilla between the arm and breast, in order to approximate more firmly the fractured extremities of the clavicle.

Gentle purgatives have been administered with good effect, and she is allowed a liberal quantity of wine daily. Union of the fractured ends of the clavicle is rapidly going on.

ST. BARTHOLOMEW'S HOSPITAL.

Partial loss of vision occasioned by external violence.

In the case of partial loss of vision occasioned by external violence, which we reported in our last, the Solutio Plumbi has been applied externally, but as yet no improvement has been manifested. The patient complains of increased pain in the ball of the eye,

and his vision is even more dim and indistinct than it was on his admission.

Fungoid excrescence of the tibia.

A sickly looking man, ætat 38, was admitted into this hospital last week, under the care of Mr. Lawrence, for fungoid excrescence of the leg. The excrescence is situated on the anterior part of the left leg, a few inches below the articulation of the knee-joint. It first made its appearance eight months ago, and gradually increased in size till it arrived at its present enormous dimensions. It is exceedingly prominent and its surface is very uneven; it is soft, vascular, and yielding. There can be no doubt of its connexion with the tibia.

Mr. Lawrence is of opinion, that amputation must be resorted to as preferable to extirpation of the tumour. The latter operation, he remarks, would prove as distressing and painful to the patient as amputation, and its success would be very precarious. In an experimental point of view, extirpation of the tumour, and erosion of the periosteum of the tibia, would prove highly interesting; but it is greatly to be apprehended that amputation of the leg would be afterwards necessary, and the patient would thus be exposed to the inconvenience and distress of a double operation.

It is most probable that amputation of the limb will take place immediately.

The general health of the patient, since his admission, has not been good, nor is his constitution, which is very much debilitated, likely to assist him in surmounting the effects of the operation.

French Hospital Reports.

Instantaneous Strabismus.

DEVERSENNE, aged 32, was admitted into the Hôtel Dieu, complaining of great weakness of sight; every object that he saw appeared to be doubled, and not situated upon the same plane; he complained of

severe headach over the left eye. On the following day an anormal direction of the ball of the eye was remarked, it being turned inwards. He was ordered to be bled, to be kept quiet, and to have a pediluvium night and morning. Four days afterwards he could see objects distinctly; the dylopia and headach continued.—*Persstet*. A fortnight afterwards a blister was applied over the left temple, which relieved the headach and the accompanying fever. From this time he improved rapidly, the only time when the dylopia was at all apparent being early in the morning.

Previous to his admission he had been affected with venereal symptoms, and had contracted a gonorrhœa the night before; all these may therefore have proved a strong exciting cause of strabismus. M. Sanson considers venereal excesses to be the cause of this affection, and relates two instances, one in which dylopia came on during the emission of semen, and in the other forty-eight hours afterwards.

Chronic ophthalmia.

Belard, aged 23, after having worked several nights by the light of a lamp, reflected from a globe of crystal, was attacked with most intense supra-orbital cephalalgia, and felt an itching over the external angle of the eye, and an acute pain, lasting only for a short time, and the conjunctivæ were red and injected. Six weeks afterwards the eye-lids were swelled and puffy, the conjunctiva generally tumefied and crossed by numberless vivid red lines. The eye was very sensible to light, continually shedding tears, and the patient complained of great pain and heaviness over the whole supra-orbital region. Rest, low diet, pediluvia night and morning; and ten leeches over the internal surface of the eye-lids. Three days afterwards there was bloody ecchymosis over the eyelid, from one of the leech bites. On the following day a blister was applied to the nape of the neck, and shortly afterwards he left the hospital with

but slight traces of ecchymosis over the conjunctiva.

Brass Dust on the transparent Cornea.

Devit, aged 52, was admitted into the hospital with ophthalmia, arising from fine particles of brass lodging on the transparent cornea. The eyes were painful, red, and highly injected, constantly secreting tears. By the aid of a lens some small dark and opaque bodies could be seen on the cornea, and immediately around, the vessels of the part were more highly inflamed and reddened. By means of a fine lancet the foreign particles were removed. His eye was ordered to be repeatedly bathed with cold water, and a warm pediluvium night and morning. By these means he was soon restored.—*Lanc. Fran.*

BOOKS.

A Treatise on those Disorders of the Brain and Nervous System which are usually considered and called Mental. By DAVID UWINS, M.D. 8vo. pp. 235. Renshaw and Rush.

Principles and Practice of Obstetric Medicine. By DAVID D. DAVIS, M.D., M.R.S.L. Part XXII. John Taylor.

This valuable work maintains its high character in deep research, learning, and practical experience; it is without a rival: it should be in every medical library in the kingdom.

CORRESPONDENTS.

Dr. O'Beirne.—We regret to be compelled again to postpone the Reply to Mr. Salmon. The great portion of our space occupied by the important documents relating to the Colleges of Physicians and Surgeons, must plead our excuse.

If *Mr. Roberts* will publish the Dictionary he is perfectly welcome to the task.

Dr. Hancock.—The new remedy has failed in the case alluded to.

Chirurgus's suggestion is not new.

A. B.—We cannot publish the "Aphorisms." Sir Anthony Carlisle and the Baga-boos would subject us to an action.

M. R. C. S. is received.

Literary Intelligence in our next.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

SATURDAY, AUGUST 24, 1833.

Vol. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE L., DELIVERED FEB. 8, 1833.

GENTLEMEN,—There are two or three things which I wish to mention before proceeding to dislocations of the thumb, and which I ought to have mentioned in the last lecture.

First, then, I ought to inform you that a particular kind of bandage is sometimes made use of for fixing the chest in the reduction of dislocations of the shoulder; there is an aperture made in it for the arm to pass through, and when applied it serves both to fix the chest and hold back the scapula. Such a bandage may be constructed in a minute, by merely making a slit in a piece of strong linen; you see a representation of it in this plate.

The same engraving shows you the direction in which Sir Astley Cooper makes extension in dislocations of the shoulder into the axilla, and at the same time, you may notice that the extending and counter-extending forces must be directly opposite to each other.

Another thing that I ought to have adverted to yesterday evening, is the old and by no means a bad method of reducing dislocations in the axilla, by placing the surgeon's heel in the arm-pit, and making extension from the hand or wrist, as represented in the engraving before us. This is a very ancient mode of reduction; the heel being placed in the axilla not only fixes the chest, and keeps back the shoulder, but also constitutes a fulcrum, on which, by the lever-like motion of the limb, the head of the humerus can be directed into the glenoid cavity of the scapula, while the surgeon at the same time makes the extension,

not as exhibited in the plate, but at the wrist. In the plate, the extension is represented as being made at the lower part of the humerus, in order to fulfil the principle, so much approved of by some surgeons, of bending the fore-arm, in order to relax the biceps. This latter plan is occasionally followed in England, but in some other parts the surgeon usually keeps the arm in a straight position, and makes extension at the wrist. By these means, gentlemen, the head of the humerus is dislodged from its situation; and inclined towards the glenoid cavity.

The plate above this represents the method of using the bone as a lever, by placing the knee, as a fulcrum, under the upper part of it, and depressing the lower end of the bone. If the patient be faint, intoxicated, or from any other cause weakened, the reduction may generally be effected almost without any extension at all, and even when extension is employed, this last method is a very good one, besides being simple.

When the humerus is incompletely dislocated, and remains fixed on the outside of the coracoid process, the reduction is effected on the same principles as are observed when the head of the bone is thrown to the inner side of that process, and after the reduction, it is advisable to apply a compress in front of the head of the humerus, just on the outside of the coracoid process, supported by the spica bandage, which is to be passed behind the shoulder, and in front of the chest, in the manner I have described to you on a former occasion. The design of the compress and bandage is to keep the head of the bone from inclining forwards again. But, gentlemen, this is a rare dislocation. Perhaps keeping the arm quiet in a sling would prevent every chance of a return of the displacement, particularly if care were taken to avoid all sudden movements of the arm backwards; however, as another security, you may employ the compress and spica bandage.

In speaking of lateral dislocations of the elbow, I ought to have mentioned that the most common is that, in which the ulna is

forced outwards into the place of the radius, which is driven off the articulated surface of the humerus altogether. Now, in this case, as there is no suitable cavity behind the humerus for the reception of the olecranon, neither extension nor flexion can be completely performed, and the nature of the case is sufficiently obvious from the extraordinary projection on the inside of the arm, formed by the greater articular surface of the humerus being uncovered; while the radius itself forms another remarkable projection over the external condyle. The reduction of all dislocations of the elbow is generally easy. In France, surgeons commonly fix the chest and shoulder, in the same manner as is done in the reduction of a dislocation of the upper head of the humerus, and having thus made their counter-extension, they apply their extending means to the wrist.

I noticed yesterday evening, the disputed point respecting the possibility of a dislocation of the carpus from the radius without a fracture, and I showed you an engraving of Cruveilhier's, in which such a dislocation was exhibited; the preparation, represented in the plate, was taken from a subject which Cruveilhier dissected himself. In this instance I observed to you, that the radius was driven behind the carpus, no doubt in consequence of a fall on the back of the hand; but, if we are to believe Cruveilhier's statements, which are contested by Dupuytren, this is not the only direction in which it is possible for a dislocation of the radius from the carpus to take place. Cruveilhier maintains that it may happen in the other direction, which is a much less likely event, viz. with the lower end of the radius driven into the palm of the hand. However, it merits your attention, gentlemen, that the case brought forward in proof of the possibility of such an occurrence did not arise from external violence, but from a circumstance which I explained to you in a former lecture, namely, the great power with which the granulations of burns contract; there had been a burn of the hand and forearm, and, by the force of the contraction of the cicatrix, the carpus was dislocated from the radius, in a manner that is sometimes deemed impossible as the result of external violence.

Dislocations of the thumb, gentlemen, are deserving of attention, because they are exceedingly difficult to reduce, especially those of the first phalanx from the metacarpal bone. There are some persons who have the ligaments of this joint so loose, that at their option they can not only dislocate the first phalanx by the action of the flexor muscles, but even replace it again by the action of the extensors. You might suppose from this circumstance, that there would be no difficulty in reducing a dislocation of this joint, but remember, that in these instances of spontaneous dislocation and reduction, the ligaments are remarkably loose. Sometimes this may be the result of disease, or the neglect of

a dislocation which had been reduced, but the bone will not be well supported in its place.

In the common dislocation of the thumb, the head of the first phalanx is thrown on the back of the head of the metacarpal bone, so that the first phalanx projects backward, while the head of the metacarpal bone inclines towards the palm, the thumb remains without the possibility of being straightened, and the second phalanx is fixed in the bent position. There is no laceration of the lateral ligaments in this dislocation, and it is on this account that the reduction is so difficult; for the wedge-shaped head of the first phalanx glides with its narrow part through the aperture between the lateral ligaments, and brings the broad part within them. Thus the first phalanx is completely and firmly wedged between the lateral ligaments, which must therefore be considered as forming the principal impediment to the reduction. Indeed, we sometimes cannot succeed by any common means in effecting a reduction. The muscles of the part also being strong, form some resistance to the reduction, especially as the surface for the application of the extending means is very limited. From these various causes, there is occasionally so much difficulty in the reduction, that, in a case in St. George's Hospital, about forty or fifty years ago, extension was made with such force, that the thumb was pulled off. At that period Mr. Bromfield was surgeon of that institution, and the case is alluded to by Mr. Hey, of Leeds, in his *Practical Observations on Surgery*. About a year and a half ago, a young man came to my house with this dislocation. He was sent to me by Mr. Hughes of Holborn, who had tried in vain to reduce it. Wishing Mr. Hughes to be present at the reduction, I desired him to call upon me in the afternoon, that we might try our skill together; but in the meantime, the patient happened to meet with a relation who was a surgeon, and who reduced it for him. I inquired how this gentleman succeeded, and was told that he fixed a piece of tape round the thumb, and secured it by the *clove-hitch* knot, which is one in familiar use amongst sailors; he then fastened a common street-door key to the tape, and, of course, was thus enabled to make extension with considerable force, and with success. In fact, I had been thinking of trying a very similar method. Sir Astley Cooper, in his work on Dislocations, gives us a drawing of his plan of reduction. He first puts round the thumb a piece of soft wet leather to prevent the skin from being injured, and then applies tape over it, which he secures by the knot I have alluded to. If you could not make this kind of knot, the one proposed by Mr. Hey, and which I explained in a former lecture, would answer as well. It seems that the sailor's knot differs from Mr. Hey's chiefly in there being two circles, or nooses made, instead of one. Mr. Hey sometimes succeeded in accomplishing the reduction without making any extension at all, merely by

pressing the head of the first phalanx towards the metacarpal bone. Indeed, it is easy to understand, that if the broad part of the bone were confined behind the lateral ligaments, the more the extension employed, the greater would be the difficulty of effecting the reduction. Sir Astley Cooper recommends the first phalanx to be bent as much as possible, before the extension is made.

Sometimes the dislocation is in the other direction, and the metacarpal bone is at the back of the first phalanx; then there is no difficulty in effecting reduction, at least Mr. Hey states, that such was the result of his experience.

The *second phalanx* is sometimes dislocated backwards; and in compound cases of this description, Sir Astley Cooper recommends cutting off the articular surface of the first phalanx. After the reduction of either of the above mentioned dislocations, the joint must be supported with pasteboard, or soap plaster and tape. Then, after a fortnight, you may begin to employ passive motion. With respect to dislocations of the elbow, also, I ought to have mentioned, that the joint should not be kept motionless very long, as ankylosis would be the consequence. At the end of a fortnight, therefore, it is advisable to have recourse to passive motion, by bending the elbow and rotating the radius gently; at all events, three weeks should not be allowed to pass, without this practice being observed, and thus the formation of a stiff joint will be prevented.

The phalanges of the fingers are most frequently dislocated backwards; the reduction is very easy; a little extension soon replaces them.

It has been proposed, when the reduction of the dislocation of the first phalanx of the thumb cannot be effected by ordinary modes, to divide one of the lateral ligaments with a couching needle. The most experienced surgeons, however, object to this practice, on account of the frequency with which tetanus is observed to follow injuries of the tendinous and ligamentous tissues about the thumb. Sir Astley Cooper thinks it far more prudent even to let the dislocation remain unreduced, than run the risk of so frightful and unmanageable a disease as traumatic tetanus. Other surgeons have recommended cutting off the head of the metacarpal bone with a small saw, or a pair of cutting pliers, which is perhaps better than dividing one of the ligaments. But I think that, by attending to the directions given you in this lecture, and by perseverance, you will generally succeed in accomplishing the reduction.

It is observed, that compound dislocations of the thumb frequently lead to tetanus—so frequently, indeed, that some surgeons have thought it advisable to amputate in all such cases, rather than attempt reduction; but in this counsel I am not disposed to agree; for, from the observations, which I have delivered on the subject of traumatic tetanus, you will

understand that amputation is a very uncertain means either of preventing or curing this disorder.

Dislocations of the vertebræ.—The next dislocations we come to, gentlemen, are those of the vertebræ, or of the spine. The dorsal and lumbar vertebræ have such extensive articular surfaces between their bodies, and their ligaments are so strong and numerous, and the motion between any two of them so trivial, that they hardly can be dislocated; and, indeed, Sir Astley Cooper, who is one of the most experienced surgeons in the world, states, that he has never seen a dislocation of the dorsal or lumbar vertebræ unaccompanied by a fracture of the oblique or articular processes; never from a simple laceration of the intervertebral substance, unaccompanied by a fracture of the processes or body of the bone. You will generally find that the dislocation occurs in the way described in my observations on fractures of the vertebræ:—you have fracture of the articular processes and of one or more of the bodies of the vertebræ, with dislocation of the articular process of one vertebræ from that of the next. But, a case of dislocation, arising from a laceration of the intervertebral substance alone, may be deemed an impossible event in the whole of the lower part of the spine. But, in the upper part of the vertebral column, there may be a dislocation of the vertebræ unaccompanied by a fracture, because the articular surfaces of the bodies of the cervical vertebræ are less extensive, and the spinous and articular processes less oblique. At St. Bartholomew's Hospital, there is a preparation in which a portion of the intervertebral substance is lacerated, between the fifth and sixth cervical vertebræ, with a partial separation of those bones from each other, and a dislocation of the articular processes on both sides. There is another instance in the museum of the same hospital of partial fracture of the bodies of the two lower cervical vertebræ, accompanied with dislocation of the articular processes. But the case in which there was dislocation and no fracture of the articular or oblique processes, is sufficient to prove, that there may be dislocation of the upper vertebræ without being accompanied by any kind of fracture. That case has been described, by Mr. Lawrence, in the *Medico-Chirurgical Transactions*, and the preparation is, as I have stated, in the Museum of St. Bartholomew's Hospital.

The treatment is not different from that which I described for fractures of the spine. In truth, the case is exactly the same as what I have treated of. You will find, in the last volume of the *Medico-Chirurgical Transactions*, a case recorded, in which the body of one of the dorsal vertebræ was fractured, and, at the same time, there was a dislocation of one of the articular processes of that bone from the corresponding articular process of the first lumbar vertebræ, without fracture of them; so that you may have dislocation of the arti-

cular processes even so low down as the point specified, without fracture of them.

Dislocations of the head.—There is no case on record, in which the os occipitis has been suddenly dislocated from the atlas by external violence; they are tied so firmly together that such a case has never been met with. Of course, it would be fatal if it were to happen. But there may be dislocations of the os occipitis from the atlas in consequence of disease. Now, this kind of displacement generally arises from a scrofulous caries of the joint, or of the atlas itself. There are also cases on record, in which exostoses from the occipital bone, or from the atlas, or from the neighbouring petrous portion of the temporal bone, have led to displacement of the atlas;—such cases are to be found in the annals of surgery. Here, of course, the space for the medulla spinalis is diminished, yet is not rendered sufficiently narrow to produce fatal consequences; and there is room enough for the spinal marrow, notwithstanding the displacement of the os occipitis. If the patient live long enough under these circumstances, anchylosis of the atlas to the os occipitis may follow, the anchylosis sometimes extending to the dentata and to the vertebrae even below that. There are several specimens in this Museum, which I have already shown you, and which I will exhibit to you again when I am on the subject of anchylosis, in which this sort of bony consolidation is illustrated. I have no doubt they were taken from persons who had had scrofulous disease of the bones concerned. Now, the symptoms of scrofulous disease of the upper cervical vertebrae, leading to displacement of them, were first accurately described by Professor Rust of Vienna, and subsequently to his publication, a good account of them was drawn up by Mr. Lawrence, and inserted in the *Medico-Chirurgical Transactions*. You will find, that most of those, who suffer from this sort of disease, are young subjects, as is the case with the generality of scrofulous patients. I have had several cases of it within the last three or four years, and these were all in young persons, two of whom were girls. At the Bloomsbury Dispensary, we have a boy, who has been under my care two or three years with this disease, which I think will terminate in anchylosis.

The symptoms of this affection are great pain on moving the neck or turning the head; after a time more or less difficulty in swallowing is felt; if you press on the part, the patient experiences great agony; the voice is hoarse; and there is oppression of the breathing; but the most characteristic symptom, when the patient is not lying down, is that he is almost always found supporting his head with both hands placed under the lower jaw, either because motion of the head gives him pain, or because the support of it gives him relief. After some time, the patient mostly becomes afflicted with vertigo, or is attacked by convulsions, which suddenly carry him off, or

he lingers for a considerable period, and dies exhausted in a state of hectic. Sometimes, before the fatal termination, you may feel a kind of crepitus in the situation of the disease.

The treatment of this particular case is conducted on the same principles as that of other scrofulous diseases of the bones and joints, that is, if there be pain and inflammation, you apply leeches to the part, and if the affection partake of a more chronic character, you use either an issue, the moxa, a blister, or a seton, to keep up a discharge from the neighbouring parts, and also to excite a counter-irritation, which may stop the morbid process in the bones.

Dislocations may take place between the atlas and the vertebra dentata. The rotatory motion of the head is performed by the atlas moving on the dentata, or rather by the former bone and the os occipitis revolving on the latter. Hence, when the rotatory motion is carried beyond a certain point, a dislocation is the consequence. Here, then, gentlemen, a dislocation may be produced by external violence, though not between the atlas and occipital bone; and, in fact, many cases on record prove the possibility of a dislocation between the atlas and dentata. If the ligament, which ties the processus dentatus to the edge of the foramen magnum, receive a violent twist, by a forcible turn of the head to the right, the left side of the dentata may be carried in front of the corresponding articular process of the atlas, while the right side of the dentata is found behind the corresponding articular surface of the atlas. When the processus dentatus is dislocated from the space between the transverse ligament and the body of the atlas, it will press upon the medulla oblongata and spinal cord, and produce immediate death. Here you must understand, that the processus dentatus does not quit its situation by a rupture of the transverse ligament, but it slips under it. Sometimes, however, the dislocation of the processus dentatus backwards may be preceded by a rupture of the transverse ligament; but that can take place only in two ways; first, by a fall with great force on the occiput, as happened in a case recorded by Boyer; and, secondly, by a violent fall on the chin, as mentioned by Sir Charles Bell. In these circumstances, you may have a rupture of the transverse ligament, and a direct displacement of the processus dentatus backwards. In children, the processus dentatus is particularly weak, and therefore liable to be broken; indeed, in any subject, in whom it is more slender than usual, it may be broken, and then the lower portion of it, passing under the transverse ligament, makes fatal pressure on the spinal marrow. In consequence of this process not being fully developed in children, and in consequence too of the ligaments being weaker in them than in adults, the common trick of lifting them up by the chin and occiput ought to be censured, for it has led, in many instances, to

a sudden displacement of the processus dentatus, and instant death.

As these cases are inevitably fatal, it is unnecessary to say any thing about their treatment. We do hear, it is true, of dislocations of the head being rectified; but these are not the same description of cases as I have been alluding to; they are merely examples of the displacement of one of the articular processes of the cervical vertebræ, which has been erroneously called a dislocation of the head; but this is, as you must immediately perceive very different from the serious case I have been describing. A cure of such displacement of an articular process of the cervical vertebræ is possible, and Desault actually succeeded in reducing an accident of the kind, by fixing the shoulders, and inclining the spine in the direction opposite to that in which it was thrown.

Dislocations of the ribs.—The ribs, gentlemen, cannot be dislocated at their vertebral extremities; no case of this kind is known to have occurred; but sometimes a separation of the ribs from their cartilages takes place, and then the bone is generally displaced outwards. You may read in Sir Charles Bell's Surgical Reports, the particulars of an interesting case, in which most of the ribs were dislocated in this manner, in consequence of the person being pressed between a post and a wagon. Dislocation of a single rib is sometimes met with. The proper treatment consists in the application of a long piece of pasteboard wetted, so as to fit the part accurately, and over this a broad roller should be applied, or a piece of linen, which is to be laced. When the pasteboard becomes dry, it forms an exact case for the part, and fits so closely as to prevent all motion of the end of the rib. Here it is also necessary to bleed the patient freely, as there is a chance of the supervention of inflammation of the chest, and even of the abdomen, for the violence, producing such a dislocation, is always very great; and, when a person is jammed between a wall or a post and a waggon, the contusion of parts is frequently not restricted to the chest.

Gentlemen, I will go on with dislocations on Monday evening, and hope to be able to finish them on Wednesday.

CLINICAL LECTURES,

DELIVERED AT THE

HOTEL DIEU, IN PARIS,

During the Session of 1832-33.

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

PATHOLOGY AND TREATMENT OF BURNS.

(Continued from p. 74.)

ELEVENTH CASE.—*Epileptic, burns of the four first degrees of the entire right side of the face and neck, and upper part of the chest*

—*Severe accidents—Profuse suppuration—Cured on the ninety-fourth day—Twelve epileptic attacks during the period of treatment.*

—Marie Floret, aged 40, of delicate constitution, subject to epilepsy for some years. Having, from this affection, been burnt five times, was admitted into the Hôtel Dieu for a new burn occupying the right side of the neck and the upper and anterior surface of the chest. It arose from her falling with her face in the fire during an attack of epilepsy. The eschars were large, deep, black, and hard to the touch. The burns of the two first degrees were but of small extent. She was in a state of great delirious excitement; pulse small and quick; respiration short and interrupted; great thirst; convulsions of the lower limbs. She was bled, and leeches were applied to the base of the cranium; revulsive and antispasmodic medicines were given; sinapisms to the feet, and an injection per anum. Cataplasms were applied over the eschars, and some light dressing was placed over the burns of the second degree, over which a light covering of charpie was placed to absorb the discharge. By this treatment the dead parts soon separated, and no accident happened during the time. Under the eschars was a wound of very good appearance. The discharge was at first very profuse, but soon diminished, and the cicatrix soon began to form. The profuse granulations were checked by proper remedies. As the suppuration decreased and the cicatrix increased, the cataplasms were changed for a light dressing with charpie, and convenient compresses and bandages.

TWELFTH CASE.—*Mental alienation—Burn of the right hand to the fifth degree—Cure of both affections.*—Clinard, aged 30, of a good constitution, was affected with mental alienation from severe distress. Active treatment restored her to reason, but she remained low and dejected. She was a servant: left the place where she was residing and came to Paris. Finding herself on one occasion alone, she made a large fire in a frying-pan, and put her hand on the burning coals. On the following morning she was brought to the Hôtel Dieu. The right hand was burnt down to the bones, everywhere were black, thick, and hardened eschars, separated only by some bloodless crevices on the dorsal surface; they extended only to the middle of the metacarpal bones. The other surface was covered by a large bladder filled with serum. There was a vivid red circle around the wrist, which still retained its free motion; the thumb and fingers were bent upon the hand; a joint of the ring finger and the little finger were exposed. The agitation of the patient was extreme, the face flushed, the eyes fixed, and the delirium continuing, which rendered it necessary for her to be confined. General bleeding, mustard pediluvium, light dressing, poultice over the whole hand, phlyctenæ opened without injuring the epidermis. On the third day fifteen leeches

were applied to the mastoid apophysis; pediluvium and injections. On the fourth day, seton over the nuchæ, purgative lavement. On the seventh day the eschars began to separate, and it was hoped that the tendons were not injured. There was a slight fœtor in the discharge; cataplasms were continued. On the eighteenth day the cries of the patient were not so violent; and when her attention was strongly fixed she would answer. By the thirty-eighth day the mental alienation had completely left her, and she was much surprised on learning the nature of her accident. The last phalanges of the ring and little finger have fallen off, as have also the eschars. The cicatrisation has commenced in some places, and small portions of dead tendon have come away with the dressings. The flexion of the fingers is less; they have been kept in an extended position that their flexion might not be increased by the growth of the cicatrices, and that the fingers might not contract adhesions. From this period nothing retarded the cure of the case; no further return of mental alienation presented itself, and she was discharged cured, being recommended to keep the seton open in her neck.

THIRTEENTH CASE.—*Burns from the first to the sixth degree on the left side of the face, and of the fifth degree on the external part of the left shoulder—Destruction of a portion of the parotid gland—Salivary fistula—Necrosis of a portion of the zygomatic arch—Cure.*—A portress, aged forty, and of bad health, subject to a sensation of swimming in the head, was seated near a charcoal stove. Being suddenly seized with giddiness, her left side and shoulder fell upon it. On the following day she was brought to the Hôtel Dieu. One burn extended from the zygomatic arch to the base of the inferior jaw, including the external angle of the eye, and reached from the labial commissure to the ear. All the soft parts were converted into a black eschar, which appeared chafed on its surface, and composed of the skin, sub-cutaneous cellular tissue, and a part of the parotid. It was surrounded by a vivid redness. The commissures of the lips and eyelids were drawn backwards, and to the left side. The second burn was over the left deltoid region; all the surface was black and scarified, and M. Dupuytren believed that the disorganisation extended to the muscle itself. That part of the face not affected was of a vivid red; there was fever and severe headach, and the burnt parts not dead were very painful. Copious bleedings, mustard pediluvia, lavements, anodyne potion, low diet. For the first few days there was little alteration; the pulse kept up its frequency, and she was again bled. On the fifth day the patient complained of a hard body in the cheek, which might arise from the eschar having destroyed the whole of the soft parts; but, on examining the mouth, the mucous membrane was found intact. On the sixth day the eschar began to be detached at the

edges; a red line separated the dead from the living parts, and a slight suppuration was established. On the eighth day there was considerable fever, tumefaction of the eyelids, erysipelas over the face, and delirium. Twenty leeches were applied to the neck, and emollient cataplasms. The delirium soon subsided, and the erysipelas appeared resolving. On the twelfth day the eschar was in a great measure separated. After a month's elapse the eschar on the shoulder separated, leaving an open wound covered with healthy granulations, which soon healed under the occasional use of the nitrate of silver and simple dressings. On the surface of the cheek, however, the progress was not so rapid. When the eschar separated, a portion of the zygomatic arch was found dead, as well as the parotid gland, a portion of which had been destroyed, and from which, during the dressings, the saliva was discharged. M. Dupuytren did not consider that this would aggravate the patient's case, and ordered the fistula to be cauterised. In the course of a few days the dead bone appeared sufficiently moveable to be extracted, which was done by a spatula lifting the dead bone from the living. After this day the extent of the wound diminished gradually, but the flow of saliva continued; and it is to be remembered, that it came from an ulcerated opening of the parotid, and not from Steno's duct. In the space of a few days the part was cauterised three distinct times, and pressure applied over it; and in less than a fortnight's space the wound and the fistula were completely healed. There remained a radiated cicatrix, depressed in the centre; paralysis of part of the cheek, and a drawing back of the eyelid and angle of the mouth on the left side. The cicatrix was red and vascular. A month after leaving the Hôtel Dieu she returned again, the fistula having re-opened. Cauterisation and compression were again resorted to, which permitted her to leave perfectly cured in three weeks.

FOURTEENTH CASE.—*Burn of the fourth degree of the right arm—Profuse suppuration—Unusual state of the wound—Cure.*—A cook, aged 18, of good health and constitution, fell asleep, and a lighted candle fell on her right arm, burning the sleeve of her gown. On examination after the accident, a burn was found, extending from the deltoid muscle to the fingers; the anterior, posterior, and inferior parts of the arm were most burnt, and the hand was covered with phlyctene, filled with serum; there were also some on the upper hand. She was bled, and took emollients, and simple dressings were applied carefully to the burnt parts. The inflammatory process passed off without any unusual accident, but after the eschars had separated, the suppuration increased so much that it was feared she would sink under it. She was supported by quinine in drinks and lavements; the whole burnt limb had soon the

appearance only of a large wound; forty-five days after the accident the wound was still of some extent, greatly inflamed, and profusely suppurating, with extensive projecting granulations, and at the head of the elbow some new skin was already forming; the catamenia had not appeared since the accident. During the next month the wound was carefully dressed with simple ointment, with a layer of charpie, and bandages to support the wound, and parts of it were occasionally touched with the nitrate of silver, and care was taken not to expose the parts too long to the air. The patient was shortly after attacked with fever, the wounds became red, and covered with clots of blood, having the odour and colour of menstrual blood. This phenomenon coincided with the time at which the menstrual fluid should have appeared. For several days leeches were applied to the vulva. The fever went off, and the wound re-assumed its usual appearance, but from the above unusual circumstances the suppuration became increased in quantity, but the cicatrization nevertheless increased; the discharge of menstrual fluid from the wound returned twice, the catamenia were not re-established, but she was bled in small quantities at definite periods of time. Her state of health continued very good. M. Dupuytren remarked on the above case, that menstruation was the performance of a simple function, which was nothing more than a sanguineous exudation; it was not, therefore, absolutely necessary that there should exist a special organ for that purpose, for it was seen that there were other exhalants or permeable tissues, through which this fluid might pass. The special organs for this secretion became complicated in proportion as the humours they separated from the blood differed in character from this secretion. Secretions were complicated functions, which could only be performed through special organs, more or less complicated; exhalations were simple functions, which might take place from any structure, because there were permeable or exhalant tissues every where. These latter were therefore subject to greater variety than the former. How difficult was it to supply a secretion which was stopped, as with the urinal secretion, which could not be brought on through the skin, and how comparatively easy was it to restore an excretion, as with the menstrual fluid in the above case.

OF THE DIFFERENT CAUSES OF PERMANENT RETRACTION OF THE FINGERS, AND OF THEIR DIFFERING DIAGNOSTIC.

The first case which I shall offer to your notice, remarked M. Dupuytren, is that of an old porter, aged seventy-four, who, for some years past, has been a street-sweeper. Five or six years ago this man was wounded in the palm of the hand by a piece of wood, but it is only within the last two years that he has re-

marked a retraction of the middle and ring fingers of the right hand, since when the disease has much increased. He supposes the injury to arise from a severe cold which he felt during the course of a rigorous winter. The fingers to-day are bent nearly to one-fourth. It is impossible to retract them, employ what force you will. Two tight, hard, and projecting cords pass from the middle of the palm to the base of the contracted fingers. When any efforts are made to extend these, they project more, and the thin tendon of the palmaris muscle is seen to be stretched along the inferior portion of the fore-arm. I have chosen this case of true retraction of the fingers in order that the distinction may be clearly seen between it and those cases that simulate it.

In other cases one or more fingers may be bent on the hand without there being any wrinkling of the aponeuroses. There may then be only an alteration in the phalanges, as may be noticed in the report of the two following cases.

A boy, aged 14, was placed under the care of M. Sanson for a white swelling of the tibio-tarsal joint. On examining him, it was perceived that he had retraction of the little finger of the left hand, which he remembered up to his earliest years. The finger is curved in the demi-arch of a circle, the first phalanx is immoveable on the second, and the second on the third. It is impossible to move the one on the other, but the articulation of the first phalanx on the fifth metacarpal bone is perfectly free. There is no starting tendon here, consequently it is a case of affection of the phalanges, and not of the palmar aponeurosis.

The symptoms of the second case are precisely similar; there is the same absence of starting tendon, the same mobility of the metacarpo-phalangeal joint, the same immobility of the second phalanx on the first and of the second on the third; these, therefore, are the particularly distinguishing signs of this affection, and by which an ankylosis of these articulations may be known.

The contraction of a cicatrix from a wound may simulate a cord, but this is superficial, and the cause of it is otherwise known. The fourth case before us is one in which the two last fingers are bent on the palm of the hand, they may, however, be easily straightened back; there exists no cord; the phalangeal and metacarpo-phalangeal articulations are all free. By what then is this constant flexion of the fingers caused? The patient received a sabre stroke on the back of the hand, the extensor tendons of the two last fingers were cut, the divided ends did not unite, and the flexor tendons being no longer antagonised, constantly draw the fingers down to the palm of the hand. In this case consequently there exists no retraction, but a passive flexion of the fingers, and an impossibility of straightening them, owing to the tendons being divided.

The fifth case is one of retraction of the

little finger, which is bent in the arc of a circle, all the other articulations are moveable, as is the first phalanx, with the metacarpal bone; there is no extended cord; the flexor and extensor tendons are here healthy; the retraction depends on a disease of the skin of the palm of the hand, caused by a contused wound from a coach-wheel; the healing of this wound was done by drawing the edges together, and not by the formation of a new cutaneous tissue; a narrow cicatrix has thus been produced, which prevents the little finger being redressed.

Burns of the palm of the hand frequently produce this effect when they are not perfectly treated, and when, instead of the fingers being in a position to keep the edges of the wound apart, and to promote the formation of new cutaneous tissue to replace the old, they are put in a situation to bring the edges of the wound with loss of substance into contact. From this cause ensue bridlings and adhesions, which prevent motion and produce retraction, without, however, causing any projecting tendons.

The contraction caused by the deformity of the phalangeal surfaces in following certain modes of livelihood is common enough. Females who are the habit of knitting much, and who keep the little finger apart from others, and forcibly bent for a long period at a time, in order to support the hemp, linen, or cotton thread, have frequently a retraction of the little finger, arising from a deformity of the inferior extremity of the first phalanx, of the superior extremity of the second, and of the corresponding extremities of this and the third. This species of deformity was much more common formerly than it is now. It is still, however, frequently observed in Germany, where the ladies of Berlin and Dresden are in the habit of knitting very much.

Here is a young girl, a lace-worker, in whom the four last fingers of each hand are retracted towards the palm. They are curved to a quarter-circle, but the metacarpophalangeal articulations move freely. They may be easily moved backwards on the hand, causing no tendon to start. But the two second phalanges cannot be returned on the first, owing to a deformed articulation of the extremities of the first and second phalanges, produced by the occupation this young person generally works at.

The next case that I shall present to your notice, is a tailor. You know that individuals following this trade have the fingers always bent. In this case it is impossible to stretch the ring finger, the attempts to do it are very painful, but there is no symptom indicating lesion of the palm of the hand. The diseased cause is here in the articulation of the second phalanx with the third, where a serous tumour has developed itself, of a nature similar to the accidental synovial cysts; the nature of this affection is easily known, it is therefore impossible to confound this case with one arising from another cause.

The retraction of the fingers caused by wounds of the flexor tendons might seem at first sight to become a true cause of retraction, but in these cases the tension of the aponeurosis is more superficial, besides, in extending the fingers in these cases the tendon of the palmaris is thrown back.

The seventh case which I shall present to you is a case of retraction of the middle finger, bent in the half-arc of a circle; at its extremity is a cutaneous cicatrix, in the thickness of which a hard, round, resisting cord may be felt, this is the tendon. The patient had a whitlow, and the surgeon who treated it cut deeply down upon it, and opened the sheath of the tendon in its whole extent, from which maltreatment has resulted displacement and retraction of the fingers.

Wounds of a joint frequently cause retraction. This is the case in the eighth patient which I now present to you, in which the indicator finger of the right hand is retracted, the third phalanx is bent on the second towards the palm, and the joint is immoveable. The patient received a wound from a cutting instrument on the back of the finger which penetrated the joint, and inflammation and suppuration ensued, and the ankylosis became complete. The other joints are perfectly moveable.

The next case is that of an engraver who received a pistol shot from a thief, which penetrated the fore-arm from before backwards on its superior and internal surface. The ball merely affected the flesh and not the bones. The cubital nerve was divided, and paralysis consequently ensued of the internal surface of the fore-arm and the two last fingers, parts to which filaments of this nerve are distributed. I was called immediately to the man, added M. Dupuytren, and laid the wound open to prevent any contraction, and dressed it as a simple wound; no accident interfered to prevent its healing, which it did in the course of a month. Paralysis only remained, with retraction of the two last fingers towards the palm. The articulations of the fingers and phalanges are free, but there is much impediment to straightening the fingers, giving the patient much pain, and accompanied with tension of the cicatrix. The flexor muscles in the spot where the injury was received having lost much substance, are shortened, and maintain a permanent flexion of the two last fingers of the hand.

Thus from amongst the observations which we have made with a view of establishing a differential diagnostic between the differing species of contraction of the fingers, we find some produced by a species of wrinkling of the palmar aponeuroses, by a deformity of the articulating surfaces of the phalanges, by a division or section of the extensor tendons, by a narrowed cicatrix of the skin, by a destruction of the fibrous grooves of the tendons, and finally, by disease or loss of substance of the flexor muscles of the fingers. I wished to offer you a pathological specimen which would

at once show you the seat of this affection of which we have been speaking. Fortunately I have specimens of the arm, fore-arm, and hand of a person who has been affected in a remarkable degree with retraction of the fingers, and I have had these parts carefully dissected, in order that you may judge of the truth of all that has been advanced upon the subject. The tendon of the palmaris and the palmar aponeurosis have been separated from the subjacent parts. If the flexor muscles had anything to do in the production of this disease, it is certain that in drawing upon them, as I do at the present moment, they would greatly increase the retraction, now this does not take place, and the cord before the two last fingers is not altered in position. If, however, the phalanges are bent backwards, the tight tendinous cord becomes very marked, but the flexor tendons are but slightly affected. If, likewise, the flexors had much influence in this affection, the section which I am going to make of them, whether superficial or deep, above the wrist, would put an end to the wrinkling of the fingers, which you see it does not do. The section of the tendons in the palm of the hand produces similar results. But if the tendons are not acted upon, the palmar aponeurosis is affected in a very different manner, for you perceive that the slightest traction of this augments the bend of the fingers towards the palm of the hand; if the fingers are at all bent backwards, the tightened cord, which is then solely formed by this aponeurosis, becomes stiff, in fact, isolated, as you now see this aponeurosis is; you can easily remark that it forms the sole obstacle to the retraction of the two last fingers. Should, however, any doubts still exist in your minds on the point, they will soon disappear, by remarking the effects produced by making a section of the palmar aponeurosis, which goes to the fingers; you perceive that this section completely restores the fingers to their normal situation and state.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

DELIVERED

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE VI.

On the Causes and Treatment of Genital Diseases.

GENTLEMEN,—In the preceding lectures, which were introductory to those on the Physical Education and Diseases of Children, I have enumerated the various diseases of the genito-urinary organs that disqualify for marriage, impede sexual commerce, cause impotence and sterility, and injure both parents and offspring.

I described the bad effects of excessive action of the genital organs induced by coition and masturbation. I shall now proceed to consider the indications of their treatment. Before I mention the modes of treating the numerous disorders and diseases caused by genital irritation, I must briefly allude to the opinions of the ancients on the injuries inflicted upon the mind and body by the loss of the spermatic fluid itself.

According to ancient and modern writers, the spermatic fluid is highly vitalised, and should be accumulated for some time in its receptacles, so that its thinner part may be absorbed and conveyed into the circulation, for the purpose of stimulating all the organs, and rendering all the functions more energetic. I have already stated, in a former lecture, that the absorption of the seminal secretion acts as a stimulant, renders man and animals more vigorous, augments their courage, excites the intellectual faculties; and that its too frequent emission destroy these salutary effects and produce diseases of debility, and sometimes various inflammations. In corroboration of this position, it may be urged, that animals at the rutting season are more savage and more vigorous than at other times; and that their flesh exhales a peculiar odour. Every physiologist has observed that the mind and body are more developed at, than before, the age of puberty; and this remarkable change has been attributed to the secretion of the spermatic, the menstrual and ovarian fluid. But, however salutary the absorption of the male semen; or the establishment of the menstrual fluid, may be, man was destined to propagate his species as well as all the inferior animals. The modern infamous doctrine to the contrary is unnatural, unchristian, and worse than beastly. The depraved advocates of anti-population may urge all the inconvenience and evils resulting from the excessive exercise of the genital functions against instinctive and natural enjoyment, but their arguments are contrary to the laws of nature and to the science of medicine. They may impose on the unenlightened multitude, but theirs is a most vicious and erroneous conclusion. It is opposed to the wise precept, "Increase and multiply," and is not more unscriptural than it is unmedical. It leads to the commission of the most horrible vices; and if followed generally, would not only exterminate society, but induce all the diseases that may be caused by the most excessive use of the genital function. It is true, that the too frequent exercise of this function will injure the mind and body; but this observation equally applies to the over-exertion of every other organ in the body; because the continual or excessive action of any organ will derange and injure the whole. Every medical practitioner who is versed in the science of disease must admit, that the monstrous and detestable practices recommended by the inhuman advocates of anti-population are infinitely more

injurious to health than even excess of sexual intercourse. It has been already proved, that the mind is more excited, and the body more convulsed; by unnatural than by natural use of the genital organs.

Every philanthropist is shocked at the frequency of unnatural crimes, which are now almost of daily occurrence, as is proved by the reports of the public press; and these, it is to be suspected, are not perpetrated by the ignorant vulgar only, but by persons of rank and education. Man, when his mind is depraved, debases himself below the level of the irrational brute, and violates the laws of nature and of Christianity. The enemies of excessive population forget that all the animated creation as well as mankind enjoy superabundance of every thing conducive to their well-being; and that even the birds of the air, "which neither sow nor reap," are amply supplied with nutriment. These men remind us of our former wise parliaments, who, in the reign of Elizabeth, passed laws to prevent the growth of London, and of the proclamations of James I. and Charles I. ordering the swarms of gentry, except those connected with the public offices, to return into the country, as "their continued residence in town raised the price of provisions, increased the number of mendicants, and brought so many loose and disorderly persons into the metropolis, that it could not be governed by ordinary magistrates." Modern experience, however, has convinced statesmen and politicians, that the greater the population the greater the power, wealth, and happiness of a nation. Reverting to the narrow-minded anti-population advocates, I may observe, they are few in number, and their wholesome checks to population are detested even by the lowest class of society. To them we may, with due deference, and without disclaiming our title to good manners, apply the words of a sacred writer to the philosophers of his time,—“they became vain in their imaginations, professing themselves wise, they became fools.” But the great bulk of mankind fall into the opposite extreme, become licentious, and induce the most troublesome disorders and the most fatal diseases, which have been already enumerated.

It has been observed, in a former lecture, that those who have injured their constitution by debauchery and libertinage are generally impressed with the conviction, that their generative functions are debilitated or destroyed. They suppose themselves impotent should they fail to accomplish their desires with a female, chosen indiscriminately. But this is very often an erroneous notion, for this reason—that if the venereal disease exists, and the organs are natural, the phenomena of procreation perfect (*erectio, penetratio, et seminis emissio*), there may be moral or imaginary, but not real or absolute impotence. There is no objection to marriage in such cases. I have known several enter into the connubial state in this condition, whose fears were dissipated and whose hopes

were realised. I have often been consulted in cases of this description, the parties being honourable and conscientious men, unwilling to commit a fraud upon others even to obtain the greatest wealth as marriage portions. Individuals of this description are generally imposed upon by the specious promises published by empirics in the newspapers, and are always swindled out of large sums, under the false pretence of obtaining a certain cure. So general is this plunder, that it is well known that some empirics expend a sum of £10,000 a year in advertisements and government stamps; in fact, there is scarcely a newspaper that does not contain their false and delusive promises. They succeed because every adult is most anxious about the vigour of his amorous powers; more especially as the genital function is almost universally abused; and as they profess to restore all defects, they are consulted by an immense number of persons, who ultimately discover, after having paid large sums, that no benefit has accrued.

The commonest observer must daily remark, that among the various kinds of imposture practised on society, quackery has been the most successful; because the great mass of mankind is credulous, or, as an able writer has said—an immense crowd of fools—“*ingens turba stultorum*.” Empirics are most successful in a great commercial country like England, and more especially in this vast metropolis, where the multitude have neither leisure nor inclination to detect imposture. The innate principle of self-preservation is so strongly entwined with the human heart, that cunning and unprincipled men, who profess to cure all diseases after physicians have failed, very easily impose upon public credulity. The love of life is predominant with all men; and when the physician pronounces disease incurable, the unfortunate sufferer will anxiously try any remedy, however useless or injurious, more especially when lauded in the newspapers as an infallible one. It is lamentable to observe that mighty engine, the press, under the controul of the venal and avaricious, who will not hesitate to publish any kind of deceptive puff for money. Another powerful protection to empirical impostors is the immense impost or duty paid by them to the state for advertisements and patents. They are legally authorised to proclaim their infallible and universal medicines, for they possess legal patents for defrauding the public. These impostors are not tolerated in any other country in Europe; neither does any other government derive a revenue from duty on patent and quack medicines, which are proposed by ignorant and dangerous persons, who venture to profess medical knowledge without a proper education. The amount of stamp duty on these useless nostrums is about £100,000 a year in the United Kingdom, and hence the toleration of empiricism, and the apathy of the College of Physicians. I need scarcely observe, that the belief in a universal remedy is

the most irrational that can be imagined. The existence of such a remedy is physically impossible. How can any rational person, on a moment's reflection, suppose that the same remedy should be capable of restoring strength and causing weakness? In many diseases the strength must be reduced, in others increased.

Nevertheless, the daily papers, "the best of all public instructors," proclaim to the world the superior excellence of universal remedies; and the public is so stupid as to believe them. Some of these remedies are so infallible, yet so simple, that the patient may take them in the form of pills, to the amount of two or two hundred at a dose; and we have, I grieve to confess it, medical men, calling themselves surgeons, and pretending to be respectable, vending these pills, which they know to be valueless, and literally conspiring to defraud a gullible public. There is, however, nothing too absurd on the part of the public in believing in the efficacy of these and other nostrums, it has always been the custom; though modern quacks are far inferior to their predecessors, as will appear by the following advertisement, which refers to the diseases under consideration. There is nothing too absurd for our nobility, gentry, and community; we had noblemen, their wives, judges, members of parliament, bishops, and all ranks, believing in the infallibility of St. John Long, Johanna Southcote, metallic tractors, and every species of the grossest humbug. I might adduce ten thousand illustrations, but one will be sufficient. The following preposterous puff was credited by many in this country*.

* TEMPLE OF HEALTH, ADELPHI.

To their Excellencies the Foreign Ambassadors, to the Nobility, Gentry, and Persons of Learning and Taste, this and to-morrow evening, exactly at eight o'clock.

The celestial brilliancy of the medico-electrical apparatus of the Temple will be exhibited by Dr. Graham himself, who will have the honour of explaining the true nature and effects of electricity, air, music, and magnetism, when applied to the human body.

In the introductory oration, the whole art of enjoying health and vigour of mind, and of preserving and exalting personal beauty and loveliness; or, in other words, of living with health and happiness in this world, for at least an hundred years, is pointed out and warily inculcated.

Previous to the display of the electrical fire, the doctor will delicately touch upon the Celestial Beds, which are soon to be opened in the Temple of Hymen, in Pall Mall, for the propagating of beings rational, and far stronger and more beautiful in mental as well as in bodily endowments, than the present puny, feeble, and nonsensical race of probationary immortals, which crawl, and fret, and politely play at cutting one another's

Oh, incredible stupidity of mankind, to patronise such consummate absurdity! It is not, therefore, marvellous, that quack specifics for restoring the injured or lost function of the reproductive organs, should be anxiously sought after by the ignorant and credulous part of the public. It is well known that the medicines which cause genital irritation, are few in number, and require to be administered with great caution. They are much more likely to do mischief than good in the hands of the ignorant. They are never exhibited by the profession until the general health is restored by proper remedies; and even then they must be tried in succession, on account of the vast difference of constitution; because what will act on one person will fail on another. I have enumerated all the supposed spermatopic and aphrodisiac remedies in my lectures on disqualifications for marriage, in the articles impotence and sterility, and cannot revert to them in this place.

I need not argue that it is the grossest deception to pretend to cure all diseases. The medical practitioner will treat all, relieve suffering, but never promises to restore or cure all his patients. He knows no such remedies as the Balsams of Life and Gilead, or the Balsams of Rakasiri, Columbo, &c. that can restore health and vigour to a constitution so diseased, its functions so destroyed, and its organs so changed by morbid action, that superhuman aid only could effect their regeneration or pristine condition. The scientific physician will not, and could not, pretend to effect impossibilities; the empiric alone professes to achieve this grand object. He holds out the balm of hope to the incurable, and the love of life, inherent in every one, induces the afflicted to grasp at any chance, just as a drowning man does at a straw.

But of all classes of diseases, those of the genital organs are the most lucrative to quacks. This arises from universal prevalence of libertinage, and from the inducements held out to dissolute young men, to persevere in their pernicious habits, under the mistaken idea, that a nostrum will finally act as a restorative.

Empirics, generally the lowest dregs of society, illiterate, ignorant of the construction or derangement of the human frame, proclaim their powers of restoring health in all cases, and of possessing more powerful remedies than the regular practitioners of the healing art. They can render the impotent vigorous, the

throats for nothing at all, on this terraqueous globe.

This apparatus, which visibly displays, as it were, the various faculties of the material soul of universal and eternal nature, is acknowledged by all who have seen it, to be by far the largest, most useful, and most magnificent that now is, or that ever was, in the world.

sterile prolific, and perform innumerable feats equally impossible.

The scientific physician or surgeon knows no specific, he employs remedies which act as counter-irritants, that set up a temporary excitement in a remote organ from that diseased, and lessen morbid action in the affected part. Upon this principle, a dose of aperient medicine will relieve a headach, not that the remedy goes to the affected part, but sets up an irritation in the stomach, bowels, and digestive organs, liver, pancreas, &c. It is true, however, that certain medicines act on particular organs, and increase or diminish their functions; but all have a physiological as well as a therapeutical effect, and influence many organs in a healthful state, before they relieve the affected part. But the first principle in the treatment of chronic or long standing diseases is to restore the general health, if this can be accomplished; and secondly, to improve the function of the affected organ or organs. The empiric begins at the wrong end, he attempts to treat local instead of general disease, and he almost invariably and inevitably fails.

It is quite surprising that our fellow countrymen, who are the most sensible and intelligent nation on earth, should be so grossly imposed upon by illiterate quacks, who assume the privileges and titles of those who spend their lives in studying the nature and treatment of the illimitable diseases of the human fabric—the most complicated machine, the most varied in its uses or functions and derangements, in the whole creation. As well might a lowly workman cast an artist's glance over the vastness of St. Paul's, and attempt to appreciate its exquisite beauties, as an empiric to comprehend the corporeal edifice of man, and estimate the beauties and harmonies of its perfectibility, or the innumerable derangements to which it is liable. The professors of the science and art of medicine, whose minds are enlarged by the best education, whose study is constant, whose observation is the most extensive, whose reflection on the multiplied experience of their predecessors is indefatigable, very often find it a matter of difficulty to detect and treat diseases; and it is the unlettered empiric only who can untie the gordian knot, and overcome all difficulties in the practice of medicine.

The spirit of reform is abroad, and these villains will be put down. I admit that they sometimes succeed in sexual diseases, because many persons imagine themselves impotent or sterile, whose organs are perfect, and whose general health is slightly deranged. These are a very numerous class; and may be benefited by local excitants, but in general such remedies are urged too far by those ignorant of their proper doses, and temporary excitement is produced; but this is followed by a proportionate collapse or want of power, and the remedy proves worse than the disease.

It is deplorable to think that the treatment of diseases of the genito-urinary organs, the most fatal to mankind, or of those maladies that strike at the root of population, should be almost entirely in the hands of the most illiterate of the community, though we have a College of Physicians, with ample powers to abate this monstrous and inhuman evil. No rational man can, on mature reflection, suppose, that an unlettered empiric can equal a scientific medical practitioner in the treatment of diseases, and no individual of an enlightened mind can allow himself to be so deluded. But the bulk of mankind is unenlightened, and therefore the victims of impostors. You must not be surprised when you discover hereafter that some of your patients have been deluded by empirics, and ultimately apply to you for advice. You should not feel angry at such applications, but pity those who are so weak in mind as to be deluded by newspaper puffs. Though you must naturally despise such deception, you are always to bear in mind, that the noble science you cultivate is ever the harbinger of good, and always subservient to the interests of your fellow creatures. Look with compassion on the frailties of our nature, and show that pity for the affliction of our species, which formed a noble trait in the characters of your predecessors. When the victims of sensuality and quackery apply to you, afford them consolation and relief, and treat them on the established principles of our science.

When masturbation is practised after the age of puberty, we should direct all our attention to the mind for its removal, because it is reflection and meditation upon amorous pleasure which excites the mischief that we have to combat. The seat of disorder is in the mind, and the effects of it in the body. We should explain to the unhappy patient the enormity of his crime, that it is contrary to religion, nature, the best interests of society, and to his own health. We should explain to him that it enfeebles his mind and body, destroys health, unfits him for the proper performance of all the duties of life, and injures his offspring, should he have any.

The next great precept to be enjoined is, that he make a firm resolution to avoid thinking or reflecting on amorous pleasure. He should suppress every impure idea as soon as it presents itself to the mind, and turn his thoughts to other subjects. He will be very much aided in this endeavour by engaging in some amusing and useful pursuit, which will occupy his entire attention. It is universally known that when the mind is actively engaged in literary or other pursuits, it has no time for indulging in meditation on the passion of love, or on any particular subject. Close attention to business, nourishing aliment, strengthening medicines, such as quinine, and other powerful tonics, with exercise in the open air, sea or cold bathing, and a residence in the country are indispensable to the cure.

Solitude, indolence, and idleness are to be strenuously avoided. A residence in the country, active exertion, as walking, dancing, equitation or horse exercise, hunting, sporting, swimming, fencing, and gymnastic pursuits, are advisable, whenever they can be followed or practised. A nourishing regimen, without exciting substances, such as red meats, spirituous wines, and exercise taken to fatigue; short sleep, on a hard bed, will very much contribute to the restoration of health. The patient should take repose on either side, and not on the back, as this last position excites the genital function. Libidinous dreams may be prevented by sedatives, administered at bed time. The head and shoulders should be raised, so as to facilitate the return of blood from the brain, and prevent dreaming.

The patient should be impressed with the absolute necessity of suppressing all impure ideas or meditations, and discontinuing the perusal of improper books or inspection of amorous prints. The derangements of the stomach and bowels should be removed by the ordinary remedies employed in dyspepsia and nervousness. Of all the restoratives, large doses of quinine are the best, the bowels being properly regulated, at the same time. Cold bathing, and affusion of cold water on the sexual organs, are extremely beneficial. The general health should be restored by ordinary remedies, and marriage recommended, when there is no physical impediment. Every scientific medical practitioner well knows that a vast number of the disorders of the genital organs may be removed by the aid of medicine and surgery. There are no such remedies as spermatopics, or perhaps aphrodisiacs, though many of those that act on the genito-urinary organs, were formerly supposed to possess these powers. The only rational mode of treating genital debility or disease, is to remove the cause, improve the appetite, produce more chyle or nutrition to be added to the blood, and through this fluid to all organs in the body. In this way only can health be established, and the genital organs, in common with all others, be restored to the natural condition. When we have fulfilled this indication, we may employ those remedies that have a specific action on the sexual organs. A great number of aliments and drinks have this effect on certain individuals, according to idiosyncrasy or peculiarity of constitution; eggs, oysters, wine, milk, &c., have this effect on certain persons.

The plans of treatment now recommended will be also most beneficial for those who are afflicted with diurnal pollutions, or frequent emissions of the spermatic fluid, popularly termed seminal weakness. This disease arises from irritability, or debility of the seminal receptacles, (*vesiculae seminales*), and the pressure of the perineal muscles during the evacuation of the bowels on them, will cause the expulsion of their contents. In such cases the seminal effusion may or may not be accom-

panied by the usual voluptuous sensation. Tissot describes numerous cases of this complaint, and I have met with some in which repeated emissions took place daily, without erection, but accompanied by a diminished sensation. Tonics, cold affusion on the genitals, and opiates every night, with attention to the bowels, very speedily cure this affection. But the most frequent diseases induced by the abuse of the genital function, are stricture of the urethra, affections of the neck of the bladder and prostate gland, accompanied by coldness of the scrotum, and a frequent desire to evacuate the bladder and void urine. These complaints are to be treated upon ordinary principles. It is long known that every organ whose function is injured by over exertion will become diseased; and this fact accords with the axiom, "*in eo loco quo quis peccat, punietur.*"

In the preceding lectures I have described the qualifications and disqualifications for marriage, the good and bad effects produced by the generative function on parents, offspring, and youth, and I shall now conclude this important subject, which is so influential on population, with a summary of the hygienic precepts relating to procreation.

According to the conclusions of ancient and modern medical writers, the following rules or precepts should be observed to obtain the beneficial results and to obviate the bad effects caused by the use of the reproductive function.

1. To avoid sexual intercourse until nature excites desire, and not habit.
2. To refrain from it when it induces debility.
3. To avoid it as much as possible until the body is fully developed, which is about the twenty-fifth year in temperate climates, and also when the decline of life has commenced.
4. It should be used with caution by persons of sedentary and laborious employments, those who make great mental or corporeal exertions; and those who feel weak, or want proper nourishment.
5. It should be avoided during the presence of menstruation, and the lochial or childbed evacuation, which usually continues after parturition for ten or twenty days; as under such circumstances it is highly injurious to both sexes, may cause excessive menstruation or lochia, or even mania in the female, and gonorrhoea in the male.
6. It should be used sparingly by mothers during lactation or suckling, as it diverts the flow of blood from the bosom to the womb; diminishes and deteriorates the breast milk, and injures the infant.
7. It must be avoided in a great degree by pregnant women, as it injures their health, and indirectly the infant, and it may cause abortion or miscarriage, by disturbing the womb. All mammiferous animals avoid it when the female is with young.
8. Sexual commerce, or genital excitation, is highly injurious during acute diseases, such as

fevers, inflammations, &c.; and also during diseases of the generative organs, whether they be venereal or not.

9. It is highly injurious after taking food, until digestion is finished, which may be two or three hours after repast.

10. It is improper during drunkenness, hunger, the depressing mental emotions, such as fear, grief, or whenever the mind or body is enfeebled.

11. In order to effect procreation according to nature's dictates, the mind and body should co-operate, the parties should be in good health, and have arrived at the adult age.

I have now endeavoured to explain the received doctrines relative to the propagation of healthful offspring, and shall at our next meeting consider the moral and physical management of pregnant women, and the maternal influence upon the new being or infant in the womb after conception.

In conclusion I must observe, that some persons may consider any allusion to the abuse of the genital function, especially to self-pollution or masturbation, ought to be passed over in books and lectures. I cannot assent to this opinion, and I shall enumerate many modern writers, besides all the ancient, who have noticed it. The following works have been written on the subject.

Dict. des Sciences Méd. art. Masturbation, par M. M. Fournier et Begin; Dict. Abrégé des Sci. Méd.; Dissert. sur les Maladies produites par la Masturbation, par M. Tissot; Dissert. de Masturbatione, a Gruner, 1784; Praktisches Werk von der Onanie, i. e. A Practical Treatise on Onanism, by Boerner, 1778; Dissert. de Masturbatione a Huscke, Winke fuer Aeltern, erzieher und Juenglinge, die Selbstbefuekung betreffend; Advice to Parents, Instructors, and Young Persons, concerning Masturbation, by Boetecher, 1791; Dissertatio de Signis Maustuprationis, &c., a Weise, 1792; Geschichte eines Onaniten, der sich selbstkurirthat; An abridged History of a Masturbator who cured himself, by Kurze, 1795; Von der Wahre Ursache der Selbstbefuekung und Ausschweifung in der Liebe, nebst der emzigen Heilmidl; On the true cause of Masturbation and of Libertinage in Love, with the only means to remedy them, by J. V. Rothe, 1798; Dissert. de Maustuprationis noxa, tenere in dubium vocata, a Goldstein, 1798; Ueber die heimlichen Sunden der Jugend; on the Secret Sins of Youth, by Salzman, 1799; Onanismus Medicé, politicé et moraliter consideratus, a Canestrini, 1801; Verhuetung und Heilung der Onanie; Means to prevent and cure Onanism, 1802, by G. W. Becker; Das wahre Gemelde der Selbstbefuekung, die Ursachen und Folgen; A True Table of Masturbation, its causes and effects, by Curdtsc, 1802; and Ueber das Zerstoerende Larter der Selbstbefuekung; on the Destructive Vice of Masturbation, 1802; Beddoes on Hygeia; Venus sine Concubitu, by Buchan. I might prolong these bibliogra-

phical notices to a much greater length; but enough has been given to prove the importance attached to the subject.

OBSERVATIONS ON PERIOSTRITIS, SYNOVITIS, &c.

BY EPHRAIM M'DOWELL, M.D., M.R.I.A.

INFLAMMATION of the synovial membranes, not arising from injury, is well known to be frequently very acute, to run to a great height, and to cause so much constitutional disturbance as frequently to endanger life. In the sixth case given by Mr. Brodie, we have an example of arachnitis occurring on the sudden disappearance of synovitis of the knee joint; and his tenth and eleventh cases show the fatal constitutional disturbance that may succeed to ulceration of even a small portion of the synovial membrane. But I shall endeavour to shew that there are other peculiarities attendant on this affection which deserve to be noticed. Since January, 1831, I have met with several cases of acute synovitis combined with inflammation of the periosteum to a greater or less extent, attacking different articulations with great rapidity, and causing death in several instances, apparently by exciting pulmonary or cerebral inflammations, the affections of the periosteum and joints remaining throughout undiminished. I shall endeavour to convey, as clearly as possible, a knowledge of the facts as they presented themselves.

The disease did not shift from one joint to another, but continued in the articulation first affected, when another was subsequently engaged. In the cases where the periosteum was implicated, the inflammation was obviously extended to it from the joint in which it first commenced. The affection must be more common than is usually supposed, as within the last two years nine examples of it have come under my observation. It is one of great severity, and runs its course to a fatal termination in too many instances, apparently uninfluenced by the treatment ordinarily

adopted in cases of inflammation of the joints, or of fibrous structures. In many instances it was accompanied by a train of symptoms so marked, as at once to declare its nature. It occurred with and without injury, and may therefore be considered as either idiopathic or symptomatic. Its subjects were remarkably young, being from ten to twenty-two years of age. In several instances they had been exposed to severe cold, and engaged in labour beyond their strength. In one instance it was suddenly developed on the disappearance of the eruption of scarlatina maligna; there had been much cerebral excitement, and extensive inflammation and sloughing of the mucous membrane of the fauces. On the twelfth day from the commencement of the disease, sudden pain and swelling of the right wrist occurred, and in a few hours fluctuation was evident, accompanied by considerable symptomatic fever. On the following day the left ankle joint was suddenly and similarly affected. There was almost constant screaming, till a few hours before death, which occurred on the third day from the attack of synovitis, and with symptoms indicating effusion within the cranium. And in the ninth case to be related, synovitis of the left hip suddenly succeeded to acute inflammation of the fascia of the right leg. The rapidity with which the disease passed through its different stages was so various, as to occupy in one instance but the short period of fifty hours, and in the others from four to eleven days.

The local symptoms were characterised by an intensely severe pain, aggravated by the slightest pressure or movement of the affected limb, and causing frequent screaming. The tension and swelling were so considerable, that when incisions were made to give exit to fluid supposed to exist, the divided surfaces retracted considerably, and the swollen muscles protruded. When the inflammation was situated in the deep-seated joints, there was no discoloration of the skin,

but the veins were numerous and turgid, if the articulation was superficial, as the ankle, or when the periosteum of a bone situated near the surface, was engaged, redness of the integuments occurred early, ending, as in erysipelas, abruptly. In one very acute case variola and cuticaria were super-induced, and in another a large gangrenous looking vesicle developed itself on the inflamed surface.

The symptomatic fever was in every instance violent, and characterised by great depression, by an anxious countenance, flushed, and depictive of great suffering by moaning or screaming in a very peculiar tone; headach, restlessness, insomnia, and by more or less of delirium. In the case of a young girl with diffused periostitis of the tibia, hydrocephalic symptoms set in three days before death, and she died in convulsions. The respiration in every case was short and hurried, with a slight cough, and frequently with a mucous or sonorous râle. The pulse was always rapid, varying from 100 to 180, and generally feeble. The tongue was loaded, frequently dry, and brown or red at the tip or edges, with insatiable thirst. There were frequent bilious vomiting, tenderness and fullness of the epigastrium, and always constipation and high-coloured and scanty urine. The constitutional symptoms, viewed in connexion with the local, bearing, in fact, a striking resemblance to those accompanying inflammation of the lining membrane of veins. The morbid appearances were, in some instances, vascularity and thickening of the synovial membrane, in others, fluid was found with little or no change in the synovial sac. The contained matter was either healthy looking pus, or a thin brownish-red fluid, with portions of lymph. There was found ulceration of the articular capsule, and also thickening, vascularity, and frequently extensive detachment of the periosteum from the bone, which usually presented a peculiarly pinkish-red colour. In one case the periosteum, for a considerable

extent, was coated with a reticulated lymph, resembling that so frequently seen in pericarditis. On cutting down to the bone, purulent infiltration of the cellular tissue of the muscle was occasionally found, the muscular fibres being of a very deep red colour, and no communication existing between the matter in the muscles and that found between the bone and its periosteum. This matter varied in its appearance, and often resembled perfectly healthy pus. In one instance in particular, matter flowed from the femoral vein on its being divided. In the majority of cases which I have had an opportunity of examining after death, but few morbid appearances were found within the cranium, and these consisted in an effusion of a small quantity of serous fluid into the ventricles and the arachnoid sac. The brain was either soft and watery, or very firm, the pia mater was more vascular than natural, and its redness was either diffused or in patches. In one of the cases to be detailed, it will be seen that periostitis of the orbit terminated by inflammation and suppuration of the dura mater, the arachnoid sac, and substance of the brain. In the cavity of the thorax morbid appearances were much more generally met with than in any other, and they may be described as consisting in recent inflammation of the pleura with adhesions, the lymph occasionally deposited on the surface in considerable quantity, and reticulated; congestion of, and numerous small abscesses in, the lungs, more or less contiguous to the surface, containing a perfect or imperfectly formed purulent secretion, and combined with the first stage of hepatitis, and with bronchitis.

With respect to the treatment of this affection, I have found that all the remedial means recommended by authors have failed to such an extent, that only three out of eight cases terminated favourably. It should be remarked, however, that the greater number of fatal cases had been so far advanced on admission into the hospital that the internal organs were

seriously, if not immediately engaged. But upon the whole, such experience as I have had in the treatment of this disease, leads me to place more reliance upon the following plan than any other I am acquainted with; viz., early and active depletion; early and free division of the periosteum, the introduction of mercury, so as to bring the system rapidly under its influence, and lastly, the energetic employment of means to support the patient during the suppurative stage*.—*Dub. Journ.*

OBSERVATIONS ON THE TREATMENT OF VARIOUS DISEASES.

BY ROBERT J. GRAVES, M.D.

Suffocative Catarrh.

MANY have written on the best means of affording relief when the patient seems in danger of being suffocated by the accumulation of fluid secretions in the bronchial tubes. In such cases, the secretion, instead of being scanty, is superabundant, and as long as the patient has strength, it is easily expectorated. The very abundance of the secretion, however, and the constant necessity of expectoration, interferes with the function of aëration, and at length the sufferer becomes so weak, that he coughs up with difficulty the sputa that obstruct the passage of air into the lungs. Every effort to do so fatigues him excessively, and adds to his debility; his countenance becomes more and more suffused and livid, the rattling of mucus is heard within the chest, the perceptive and mental faculties are dull and impaired, and, finally, the patient is suffocated after a painful and protracted struggle. This series of symptoms frequently attends common cold in the chest, in those who are debilitated by great age, and is not unusual in younger persons after a severe bronchitis which has lasted until their strength has been broken, and an excessive flux from the mucous membrane of the air-passage, has been the consequence of its

* The valuable cases appended to this paper we shall give in our Hospital Reports.—Eds.

long continuance. The late epidemic influenza, in consequence of the extreme and immediate debility, and the violent determination to the mucous membrane of the air-passages which it occasioned, was a disease peculiarly well calculated to produce the state of things above described, and accordingly it often terminated in suffocation from the accumulation of mucus in the lungs. This state must be carefully distinguished in practice from the dyspnoea and tightness of chest accompanying a difficult and scanty expectoration, for stimulants are often serviceable in the former but never in the latter. When the danger is from excess of secretion and accompanying debility, we can only attempt a cure by medicines calculated either to diminish the quantity of fluid to be expectorated, or by means adapted to increase the patient's strength. Practitioners have sought to effect both or either of these objects by various means. Emetics, stimulating expectorants, such as decoction of polygala, with carbonate of ammonia, balsam of copaiba, combinations of antimonials, squills, and ipecacuanha, lac ammoniaci, *mistura ferri composita*, the frequent change of the patient's position in bed, the inhalation of various vapours capable of stimulating the respiratory apparatus to renewed action, the application of blisters to the chest and nape of the neck, of actual cautery along the eighth pair of nerves, the use of wine or punch, have all proved occasionally successful in cases of this nature. Still, however, the instances of failure are so numerous and distressing, that it becomes the duty of every physician to seek for means still more efficacious and certain. Tonics and opium are well known to possess a powerful influence over the secretion of the bronchial tubes, and it has been long observed that when injudiciously exhibited, they are often observed suddenly to check expectoration, tighten the chest, and bring on the most formidable dyspnoea. A knowledge of those baneful effects induced me to hope

that these medicines might be so managed as to relieve the affection of the chest in which suffocation is the result of superabundant secretion and debility. As all practical men were agreed that sulphate of quinine and opium exhibited in the usual way had failed to produce relief in such cases, I determined to try these medicines in the form of an injection. (Three cases are related in which injections of three ounces of solution of starch, ten grains of sulphate of quinine, and twenty drops of laudanum, proved of the greatest service in restoring the patients.) In urgent cases of this nature, emetics occasionally snatch the patient as it were from the jaws of death; but they often fail, for, as has been well remarked by Dr. Stokes, the imperfect aëration of the blood frequently so impairs the nervous energy, that emetics cannot produce their customary effect upon the stomach. In such a crisis the practitioner may do irreparable mischief by exhibiting one emetic after another in the vain hope of exciting vomiting; and, therefore, when he finds that the ordinary emetic powder, consisting of a scruple of ipecacuanha and one grain of tartar emetic, has not produced the desired effect, he ought to desist from the attempt, and try other remedies. In addition to the list of those already enumerated, I beg leave to recommend a combination which I have lately used with considerable success, mustard seed and ipecacuanha. Five grains of the former in powder, with one of the latter, may be exhibited every hour, or every second hour, according to the urgency of the case. A man was evidently saved by this combination in the clinical wards of Sir Patrick Dunn's Hospital last April, after all remedies had failed, and at a time that his death seemed inevitable. A knowledge of the fact that the remedies most useful in this disease are taken from the class of stimulating expectorants capable also of producing nausea and vomiting, suggested to me the use of mustard seed. Combined

with ipecacuanha its medical qualities appear to be advantageously modified; when it is not desirable to excite vomiting the dose should not be repeated at too short intervals, but as was before observed, in bad cases of suffocative catarrh there is no danger of sickness of the stomach being produced, as was exemplified in the Meath Hospital, where a patient took with temporary benefit, and without his stomach being turned, fifteen such doses of mustard seed and ipecacuanha in twenty-four hours.

To conclude, I must observe that this form of disease will often baffle the most skilful practitioner, and therefore the remedies I recommend will, of course, like all others, frequently fail. The injection of sulphate of quinine and laudanum possesses very great powers, and for that very reason must be used with circumspection, for if exhibited at an improper period of the disease cases where expectoration is not scanty and difficult, it may produce dangerous consequences.—*Ibid.*

DR. O'BEIRNE'S REPLY TO MR.
SALMON.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN,—I shall feel obliged by your inserting the following letter in your valuable and ably conducted Journal.

I have the honour to be,

Gentlemen,

Your obliged humble servant,

J. O'BEIRNE, M.D., &c.

*North Cumberland-street, Dublin,
July 25, 1833.*

TO FREDERICK SALMON, ESQ.

SIR,—In the London Medical and Surgical Journal for the 20th of last April, you have inserted some strictures on my recently published work. Your observations are addressed, it is true, to the Editors of that Journal, but it is obviously my duty to reply to them. That duty would have been discharged long before this, if it were

not for a strong aversion which I could not avoid feeling, to replying to your critique in the only manner that its general nature and tone left me at liberty to adopt. The aversion to which I allude, arose from the strange circumstance of your not having, as I shall soon plainly show, read the work itself, at the time that you sat down to display the fallacy of its doctrines. But your character, as a successful writer on the functions and diseases of the rectum, and the weight which is likely to be attached to your opinions, on points so intimately connected with that subject, are the considerations which have at length overcome this feeling, and convinced me of the imperative necessity of exposing the weakness of the objections which you have urged against the doctrines advocated in my work. The task is an exceedingly unpleasant one, but I shall endeavour to perform it in as respectful and moderate a manner as the circumstances will permit.

You commenced by stating, that I deny "the general opinion of physiologists, that the use of the rectum is to contain fecal matter, to allow its accumulation, and to act as antagonist to the sphincter ani muscles." In limine, here are two important misstatements. I do not deny that the rectum is intended to contain fecal matter, for every one knows, that the feces must pass through it, and you will find, first, that I describe the fecal matter as undergoing, in its course through that intestine, changes in respect of situation, volume, and compactness. Secondly, that I admit that, even in the healthy state, a small quantity of excrement may be found in the pouch, but in no other part of the rectum. Again, so far from denying that the rectum acts as the antagonist of the sphincter ani muscles; I have clearly shown, first, that while the intestine is contracted and empty, its upper annulus, or extremity, and not, as has been considered, the sphincter ani, is engaged in opposing the action of the diaphragm, abdominal muscles, and mus-

cular coats of the colon; secondly, that when the rectum is forced open and filled, it contracts upon its contents, propels them into the pouch, ~~against~~ the sphincter, and out of the body, and, in doing so, again excludes the sphincter ani from receiving any impulse from the diaphragm, abdominal muscles, and muscular coats of the colon. *This view of the subject actually makes the rectum the only antagonist of the sphincter muscles of the anus.*

Having made the important misstatements which I have just corrected, you proceed to refute my views of defecation, and then to detail your own. But as your refutation is, in a great measure, conducted upon premises, which I have not laid down; and as your views exhibit little of novelty, and depend altogether on the supposed unsoundness of the only part of my doctrine that you have stated correctly, namely, that the rectum is not intended to allow the accumulation of fecal matter, I shall take no notice of either one or the other, but apply myself to this, the only physiological point that appears to be at issue between us. Before I do so, however, you must permit me to exhibit another proof shewing that you had not read my work at the time that you penned your critique. It is this:—You ask four questions respecting the rectum, namely, “Why is its form so peculiar? why is its muscular power greater than that of any other portion of the intestinal canal? why is its capacity larger at the end than at the beginning? Lastly, why are the absorbents and mucous glands so much more prevalent at this point?” Assuredly you could not possibly have read the work itself, at the time that you put such questions as these, for if you had, you would have found that it discusses the three first points at great length, and explains them, I fearlessly assert, on the only principles upon which it is possible to explain them correctly. And as to the fourth and last of your questions, I formally deny that absorbents abound more at the

lower than at the upper part of the rectum; while common sense points out, that an extra sprinkling of mucous glands would be particularly required at a point where a considerable mass of dry and solid excrement was about to pass through so small an outlet as the anus.

Reverting, then, to the question of the rectum being or not being a *dépôt* for the gradual accumulation of fecal matter, you advocate the former opinion. But how do you sustain it? By giving, as mine, an entire passage which is not to be found in my book; by omitting to notice several of my strongest proofs; and by mistaking one of the two which you have noticed, and discrediting the other. For example: you state, that I argue “that if it (the rectum) was a receptacle for feces, the accumulation of these would excite irritation in the bladder;” and after mentioning my name, you place this passage between inverted commas, as if it were mine; whereas, if you had read the work itself, you would have seen that, in adverting to the disadvantages of the rectum allowing the accumulation of fecal matter, I do not make any allusion whatever to the urinary bladder, but to that organ being mechanically prevented from discharging its contents. This is not all. By way of illustrating the truth of this supposed opinion of mine, you proceed to say, that irritation of the bladder “will happen if the rectum is not relieved of its contents.” I deny this to be the fact. I have frequently examined the rectum of persons labouring under irritable bladder, and have never found it to contain feces. It is well known that such an affection of the urinary bladder often exists without constipation; and it does not appear that the comparatively rare cases in which constipation is caused by indurated feces accumulated in the rectum, have been attended with irritability of the bladder.

Coming to the second of the proofs that you have noticed, “Dr. O'Beirne,” you say, “in proof of his theory, instances the loss of the sphincter by

syphilis, or carcinoma. Whether the former effect ever occurs I think is questionable; and surely he does not mean to say, that if this part is destroyed by the latter disease, that the patient will retain his motions as before; if so, I beg, from experience, to dissent from any such opinion, for there is no symptom of genuine carcinoma more invariable than an almost constant necessity to void the evacuations, which are passed with the most acute agony." In answer to your doubts that the sphincter ani may be destroyed by syphilis, you must permit me not only to believe what nearly thirty years spent in the study and practice of the profession have occasionally presented to my observation, but also to doubt, in my turn, that experience has shown any parts of the human body to be exempted from the ravages of that disease. Again; in reference to your assertion, "that a person whose rectum has been destroyed by carcinoma will not retain his motions as before," I have to remind you that the circumstances of his having "an almost constant necessity to void the evacuations," or of these being "passed with the acutest agony," are not those which bear upon the point in question, and for the present I shall confine myself to re-asserting, from experience, that such a person will rarely, if ever, pass his stools involuntarily, which he should do if your view of the subject were correct. I shall shortly have occasion, however, to discuss this point at considerable length, and must bespeak your indulgence until then. But why, let me ask, have you not adverted to the proofs which I have adduced in evidence of the same fact, from what is observed in cases of prolapsus ani, and after the operation for fistula in ano? How is it that you have thus noticed the first and sixth, and have not noticed either the second, third, fourth, fifth, or seventh series of proofs which I have advanced in support of the doctrine, that the rectum is not intended to permit the gradual accumulation of fecal matter? Simply

because, instead of consulting the original, you have trusted to reviews of the work.

You next proceed to animadvert upon my mode of examining the rectum, and pronounce it to be inconclusive, and "anything but a scientific exploration of the part." As far as I can collect them, the grounds upon which you pronounce this judgment may be reduced to these,—that the curves of the intestines would make it necessary to use force or pressure in order to pass them, and that this would be particularly the case in using "a straight, although it be an elastic, tube, not a third of the size of the natural calibre of the bowel." Here, however, you have obviously lost sight of the fact, that, as the rectum is contracted from its commencement to its pouch, and contracted so as to leave scarcely any cavity, the calibre of the tube must, of necessity, greatly exceed that of the rectum. If you had read the work itself, you could scarcely avoid inferring this to be the case; and you would also have seen it proved, that as the tube proceeds it is embraced so closely as to be compelled to move in the axis of the rectum, and in no other direction.

I have now arrived at a part of your critique, which would be perfectly unaccountable if you had read my work. "As to the causes," you say, "of contraction of the sigmoid flexure of the colon, the late Mr. White and myself long ago stated them to be just such as Dr. O'Beirne now describes." What is the real state of the facts? Just this: My explanation of the causes of contraction or stricture at the termination of the colon in the rectum is altogether founded on principles which every one who has, as yet, either read or reviewed the work, has admitted to be perfectly original. Is it possible, then, that either you, the late Mr. White, or any other author, could have explained the occurrence in the same manner that I have? I should think not. But are our explanations actually the same? Certainly not; for the merest tyro in

the profession has only to compare both, in order to see and be convinced that yours is as widely different from mine as light is from darkness. "I likewise have affirmed," you proceed to say, "in my writings and lectures, that I believe stricture at this part is sometimes congenital." Not having seen any report of your lectures, I can only reply to this passage by turning to the second edition of your work on the subject, in which I cannot find that you have qualified your opinion on this point by the word "sometimes." From this circumstance, it would really appear that the interpolation is of very recent date, and that you are likely to come round to my view of the matter, and which is this—that the narrow neck or stricture occasionally seen at the top of the rectum in infants and children, is not owing, as you have asserted, to congenital malformations, but produced by the same causes, and in the same way, as I have described it to be produced in adults.

Passing from the claim which you set up to being the first who made known the frequency of stricture at the termination of the colon, and which claim should, in my opinion, be decided in favour of the late Mr. White, of Bath, I come next to your observations on my opinions, as compared with those generally held respecting that disease. "Dr. O'Beirne denies," you say, "the existence of permanent stricture of the lower part of this intestine, an assertion so totally at variance with practical experience, that it is hardly necessary I should refute it. If, however, you or any members of our profession wish to be satisfied of the incorrectness of the doctor's judgment upon this point, I shall feel a pleasure in showing you, or them, numerous morbid preparations confirming the fact, in some of these the smallest bougie cannot be passed through the strictured surface." This, indeed, is coming to the point, and meeting the question in the best and fairest manner possible. Accordingly I accept

your challenge, and have written to my friends, Mr. Guthrie and Mr. Bransby Cooper, either of whom will, I am disposed to think, do me the favour of waiting upon you, and inspecting the morbid preparations to which you refer. If either of these gentlemen informs me that you possess preparations showing *distinct, thickened, and shelf-like projections* from any part of the interior of the rectum lower down than its upper extremity, I hereby bind myself to at once publicly recant my error. But if, on the contrary, either of these gentlemen should inform me that your preparations exhibit nothing more than a greater or less degree of uniform thickening of the parietes of the intestine, and extending to a greater or less degree downwards, without any distinct, thickened, and shelf-like projection internally, I shall expect you to adopt the same course. By acting thus, we shall prove that we do not contend for victory but for truth. In the fulness of this, the only true spirit of science, I am prepared to go still farther, and to invite you to examine the different anatomical museums of London, as I have those of Dublin, in order to see how far your inquiries do or do not sustain the conclusions at which mine have enabled me to arrive.

You go on to show, that the passive contraction of the muscular coats of the rectum, throws the inner or mucous coat into numerous folds, which are sometimes of a circular shape, and form prominent and irregular ridges in the bowel; and that it is from the resistance given by these folds in examinations per anum, and not, as I have shown, from the contraction of the muscular coats, that we may be deceived as to the existence of stricture in the rectum. Here, as well as in other parts of your critique, I have to complain that you avail yourself and speak of the naturally contracted condition of the rectum as if it were a fact well and generally known. But is it true that the contraction of this intestine throws

its lining membrane into circular folds? It is not; and I beg leave to remind you that Morgagni does not, as you would lead us to believe, apply the term "columns of the rectum" to circular, but to a number of longitudinal folds, which are almost the only ones found in the intestine, and which cannot, it is obvious, oppose any resistance to the passage either of the finger or the tube. These facts are so generally considered to be established by the controversy which I have lately had with Dr. Houston, and which you will find inserted in the last number of the "Dublin Journal of Medical and Chemical Science," that it is unnecessary to say more on this part of the subject.

You conclude your objections by asserting, "that the introduction of a bougie, *which assimilates to the natural calibre of the bowel*, will at all times dilate the intestine without difficulty or pain, whereas, if a small bougie is used, the rectum being irritated will contract upon it, and the action thus induced is considered to arise from stricture." Here, again, you have obviously lost sight of the fact, that the natural state of the rectum being one of forcible contraction, the natural calibre of this intestine is necessarily much less than that of the tube which I employ. I admit, indeed, that a bougie of the largest size will often pass up and dilate the healthy rectum "without difficulty or pain;" but this happens to be one of the circumstances which have so long deceived surgeons, and prevented them from arriving at a correct knowledge of the natural state and function of that intestine. How this has happened is clear, for a solid instrument of this size, by overcoming the contractile power of the muscular coats, dilates the bowel before it, and with such an imperfect sense of resistance, that operators have been led to conclude that the walls of the gut, instead of being imperiously contracted, stand wide open. For these reasons, I maintain that the employment of a tubular, instead

of a solid, and of a moderate, instead of the largest sized, instrument, is a much more conclusive and scientific mode of making examinations per anum, than that which you advocate.

Having replied to all your objections, it remains that I should point out the source from which you appear to me to have derived your acquaintance with my doctrines, and upon which you have partly depended in undertaking to expose their fallacy. The source to which I allude, is a highly favourable review of the work, which appeared in two numbers of this journal, and which, with two or three exceptions, presents a remarkably faithful exposé of my opinions and practice. That this is the only natural conclusion to be come to, is evident, not alone from the circumstances to which I have already adverted, but also from the fact of your using and quoting the precise words of the writer of that review, and never those which I employ. Permit me then to say, that this description of criticism is not only unusual, but if tolerated, eminently calculated to prove extremely unjust and harassing to authors and reviewers in general. But it is necessary, perhaps, to place this truth clearly before you. An author, for example, often sustains his views by facts and reasoning so inseparably connected, that these must be carefully considered before either the merits or demerits of his work can be fairly estimated. Such a work comes before a reviewer, who, in catering for his readers, and in justice to other writers, is obliged to compress the whole of the author's views into as small a space as he fairly can, and it is well known, that in doing so his utmost care will often not prevent him from misstating some one or other of the minute details, which, by the way, he very properly leaves to be collected from the work itself. Then comes a gentleman who has views of his own to uphold, and who does not take time to read the work itself, but, in his eagerness to assail its doctrines, trusts to a review

of it, seizes upon some of the few loose statements of the reviewer, and aided by considerable talent and reputation, succeeds in prejudicing the minds of many against views which are, perhaps, eventually found to be much sounder and more useful than his own. Finally, the author is reluctantly compelled to wade through a mass of mis-statements, misconceptions, and false positions, in order to defend his doctrines, and expose "the nakedness of the land" upon which his commentator has appeared to have found such sure footing. This is not a hypothetical case, for, if I am not grossly deceived, it is precisely the position in which you now stand with me.

From the great attention which you appear to have paid to the subject upon which we differ so widely, there are few with whom I would more willingly enter on a dispassionate discussion of its debatable points. In the few months which have elapsed since the publication of my work, it has been reviewed in six different journals, and these, together with your own ample resources, cannot fail to furnish you with abundant objections, both theoretical and practical, to the new views which it advances. Let me hope, therefore, that the extreme importance and interest of the subject, will induce you to commence such a discussion; and you may rest assured that I shall lose no time in answering any communication with which you may be disposed to favour me.

I have the honour to be, Sir,
Your obedient humble servant,
JAMES O'BEIRNE.

QUININE IN ODONTALGIA.

TOOTHACH is not unfrequently periodical, and will continue to harass a patient long, if the usual anti-odontalgics only are used. Many a sound tooth has been extracted without the least relief to the suffering. Quinine in such cases as are obviously intermittent will almost always cure the

pain as rapidly and as effectually as it does an ague. In short, all diseases in which there are periodic invasions and remissions, even in hectic and intermittent fevers, dependent upon urinary disorders, the bark seldom fails to relieve for a time, if it cannot effect a cure.

NEW THEORY OF CHOLERA.

IN our Number of the 20th of July last, we gave an extract from the "*Journal Complementary*," stating that "M. Ledeschault, of Paris, and M. Levicaire, of Toulon, consider that the development of hydrocyanic acid in the economy was the cause of cholera. Its antidote they suppose is chlorine, or liquid chloric acid, given internally. The former gentleman treated eleven patients by this method with success."

On looking over some of our earlier Numbers, we observe that so far back as February 4th, 1832, we published a letter from Dr. Murray, of Dublin, Physician to the Lord Lieutenant, in which he advanced this theory, explained the undue evolution of the ultimate atoms which combine to form hydrocyanic acid in cholera; and recommended the inhalation of ammonia diluted with the vapour of water as an antidote to the poison.

Breathing air, impregnated with ammonia, is undoubtedly a more certain corrector of prussic acid than any remedy introduced into the stomach. At all events, the priority of this theory clearly belongs to Dr. Murray, as is proved by a reference to our very *first weekly number*.

His explanation, in our Journal for July 14th, 1832, distinctly points out how such untoward developments may originate in various situations from certain electrical influences set in operation by some disproportion of the *resinous and vitreous elements* composing the electric fluid, and where derangements result from the due balance of electricity having been altered in any part of the earth or atmosphere.

PROGRESS OF MEDICAL REFORM.

IT must have struck our readers with surprise, to notice the parliamentary documents which appeared in our last, as they prove that the legislature has determined upon an efficient medical reform. The College of Physicians, with its usual Jesuitism, withheld, in the first instance, its by-laws regarding the Licentiates; but, thanks to Mr. Hume, these illegal dictates, together with many more of the Sybilline leaves in the arcana of the College, must immediately see the light. It is evident that all the by-laws of the British colleges are unjust, for otherwise the parliament would not call for them. This inquiry proves, beyond the possibility of doubt, that reform in the medical profession is at hand. We know from the most authentic sources, that all the universities in Europe and in America, will be immediately applied to, and requested to furnish their curricula, or courses of education, and the laws relating to the practice of medicine. All these communications will be carefully examined, their merits extracted, and a plan for a British faculty drawn from them. No one acquainted with the course of education in foreign countries can hesitate to prefer it to our national systems. In other parts of Europe, the student in medicine must have obtained an excellent general education before he is allowed

to commence the study of physic. He must attend all the lectures required in these countries, before he can take a degree in medicine or surgery; and when he has procured one, he is not allowed to practise, until he has diligently attended a clinical hospital for two years. He then applies for admission into the faculty, but before he obtains it, he must submit to a rigid examination before that body, composed of physicians, surgeons, and apothecaries, go into the hospital and examine three medical cases, describe the causes, diagnosis, prognosis, and treatment; or if he intends to qualify for surgery, he must perform three capital operations on the dead body; and if he seeks for the qualification of apothecary, he must prepare three medicines in the presence of the faculty, such as calomel, nitric acid, &c. No one on the Continent is allowed to practise medicine or surgery who has not obtained a licence from the Faculty of Physic, while in this country any one may practice either with impunity. When candidates obtain a degree in medicine, or a diploma in surgery or pharmacy, in our institutions, they are not required to give the slightest proof of practical experience. Their whole knowledge is theoretical, and they are at once authorised to undertake the sacred duty of treating the most complicated and dangerous diseases. It is true that students are required to produce hospital or dispensary certificates, but few of them ever attend these sources of practical and valuable information, either

regularly or diligently ; and it is notorious that certificates are given, (especially in the large hospitals, where there are crowds of students,) to those who never attended one week. The truth is, that our clinical medicine and surgery, taking it on the greatest scale, is the worst and most inefficient in the world. Though our hospital surgeons exact large fees from students, is there one amongst them who gives a weekly lecture on clinical surgery ? The physicians in general are open to this charge, and the exceptions are few in number. We sadly want the continental systems of clinical instruction, which oblige students to take the charge of patients under the superintendence of their teachers. There is little doubt but parliament will compel the introduction of this system, and adopt every thing that is valuable in the foreign schools. We look to better times, and we are convinced they are at hand.

THE CHOLERA BILL.

LEGISLATIVE wisdom has, in the present day, degenerated into a mere jest, declamation amounts, in many instances, to buffoonery, and sentiment to affectation. Proofs in abundance might be quoted in the support of such an opinion, for "great cry and little wool" is a proverb the truth of which might be applied to many of our senators. A few nights since, Lord Lansdowne brought forward his Cholera Prevention Bill, doubtless with a view to reinstate us again in all the glory of conta-

gion, contingent contagion, Boards of Health, quarantine, &c., but their Lordships, with a degree of critical acumen for which we are bound to give them due credit, quashed the intruder, and proclaimed it to be not wanted, and it died, if not of the disease it was intended to prevent, at least of one equally fatal.

Folly did not, however, rest here. Mr. Poulett Thompson was determined upon having a resurrection, and bringing the dead to life again ; the corpse was therefore placed on the table of the House of Commons, and sundry speeches were made over it ; but alas ! no sign of animation appeared, and Mr. Poulett Thompson stands a very fair chance of being appointed undertaker to this new species of monstrosity. Should the corpse move, our readers shall be acquainted with its motions.

THE CHOLERA.

SINCE our last publication, the virulence of this epidemic, though in no way abated, has not in any prominent degree increased, and we believe we are correct in adding, that the remedies employed for its relief and cure, have not so signally failed as in many instances they formerly did. The season of the year is one greatly conducive to the increase of all bowel and biliary affections, which are at present very rife, and which if neglected, generally run on to the full development of cholera. The quantities of fruit and shell-fish which are eaten, tend to irritate the mucous membrane of the stomach and bowels

in a very great degree, and to vitiate the biliary secretion, whilst the objectionable practice of drinking brandy and water irritates and inflames those parts previously weakened by a poor or bad course of diet. Wholesome meat, with a moderate quantity of vegetables, may form the usual system of dieting in those whose health is good; invalids should be careful, and abstain from all that is likely to derange in the slightest degree the functions of the alimentary canal.

SUBJECTS PROPOSED FOR PRIZE
ESSAYS BY THE ZOOLOGICAL SOCIETY OF DUBLIN.

Four gold medals are appropriated for this purpose.

1. The first medal will be given to the writer of the best essay upon the Comparative Anatomy of the *nervous*, the *respiratory*, the *vascular*, or the *digestive* systems, whether followed out through all the families of a given class, or traced from their first rudiments to their complete development in the same animal.

2. The second, to the writer of the best essay upon the Metamorphosis of Crustacea, as observable in the various genera, and as far as may be, in the several species which inhabit the Irish coast.

3. The third, to the writer of the best and most complete essay upon the General Zoology of any district in Ireland.

4. The fourth, to the author of the best monograph upon the species of any extensive division of animals found in Ireland, or in the Irish seas, with a minute description of their natural character, organisations, and habits.

The essays must be forwarded to the Secretary, with fictitious signatures, on or before the 1st of November, 1834.

It is the intention of the Council to refer the essays to a committee of

English naturalists to decide upon their respective merits.

HYDROCYANIC ACID.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I have to request the insertion of the following extract from a lecture, as pointing out the influence of the mind upon the operation of medicine, and also as exhibiting conduct on the part of an apothecary highly unprofessional.

Yours, truly,

JOHN EPPS, M.D.

89, Great Russell-street,
August 19th.

"I now, gentlemen, have to notice a circumstance with regard to this acid (prussic) that you must guard against. It is the prejudice that arises from this acid having been much used for poisoning animals, more particularly *cats*. Many weak-minded persons would be very much offended with you if you were to give them a medicine, as they say, 'used to poison cats.' They would not, it is likely, take the medicine; and if they did, the prejudice against it would make them imagine that they were injured by it. I have known several such instances. The advisable plan is, to call the acid by its more scientific name, viz., the *hydrocyanic acid*. This they will not so readily understand, and the mystery will, in this case, be beneficial; and I may add, that as long as the majority of mankind consists of fools, we must have mystery in medicine.

"I now shall mention a circumstance, which shows either the grossest ignorance or the most wicked disposition on the part of an apothecary. A patient consulted me a short time since for an affection of the eyes and a partial deafness, for which he had been under the care of the first oculists in London and Edinburgh, without deriving any benefit. After examining into the case, I found that the digestive system and the nervous system were much disordered, and I concluded, that by treating these I

should cure the *local disease*. The result verified the inference. But, in the treatment of the case, I prescribed prussic acid according to the following formula:—*Rx. Acidi hydrocyanici ad formulam Domini Scheele gtt. xxx.*; to this, water to the amount of $\bar{3}$ iij. was to be added, and the patient was to take, *three times a-day, one tea-spoonful*, having thus only *one drop* to take three times a-day. The patient's father took the prescription to his apothecary to have it made up, and the man had the unprofessional audacity to paste on the bottle the word 'Poison.' Now, what might have been the effect of this welcome information upon my patient and his parents? The parents told me, that unless they had had the highest confidence in me they would not have given the medicine to their son; and even then, they much hesitated. They gave it, however, and benefit resulted. Had these persons been *weak-minded* characters I should have been reproached for giving 'poison' to their son. The liquid was not colourless; there were other ingredients therein, so that no excuse could be drawn from this."

RELATIVE WEIGHT OF THE CEREBRUM AND CEREBELLUM IN MANIACS.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Having carefully examined the comparative weight of the cerebrum and cerebellum in forty cases, the following remarks may not be unworthy of a record in the pages of your valuable journal. The subjects affording me the opportunity of making the experiments, were between the ages of twenty and eighty-three, but principally of the middle age, and all were inmates of a mad house.

It appears that the weight of the cerebellum is not at all proportioned to that of the cerebrum. In the largest cerebrum, which weighed three pounds and eight ounces (avoirdupois), the

cerebellum only weighed four ounces and a half, whilst, on the contrary, a cerebrum that weighed only two pounds, had a cerebellum weighing six ounces and a half; and in another instance, a cerebrum of the same weight had a cerebellum weighing five ounces and a half. The weight of the largest cerebrum was three pounds and eight ounces, the smallest two pounds. The largest cerebellum weighed seven ounces, the smallest four.

From the cases taken collectively, I am led to believe that the average weight of the human brain (including the cerebellum,) is *two pounds, fifteen ounces, and six drachms*; but as all the cases exhibited relatively more or less a disproportion in their bulk, and considering they were all cases of confirmed madness, I wished to ascertain whether the same disproportion existed in other individuals who had not during their lives exhibited any symptoms of insanity.

That the size of the cerebrum in different individuals bears a different proportion to each other, is naturally to be expected, because the containing cavities vary in size, but that the cerebellum *also* bears a disproportion according to the largeness or smallness of that cerebrum, is rather extraordinary, and this as it appears, more particularly in individuals who had been afflicted with insanity.

Accordingly, I find that in the few cases I have examined, where there had been no pre-existing madness, the cerebral and cerebellic substances do bear a much more exact proportion towards each other, and when I have examined an equal number of cases, I will forward you the result, and the inference I draw from the circumstance.

I am, Gentlemen,
Your's very respectfully,
M. R. C. S.

Coventry,
August, 14th, 1833.

French Medicine.

Treatment of Amaurosis, by M. Lisfranc.—First of all we should ascertain whether there are any symptoms of inflammatory fulness and activity in the eye or head; as a matter of course such cases require depletion. When, however, we have reason to believe that the disease is one rather of debility, M. Lisfranc strongly advises us to direct our attention in an especial manner to stimulate the frontal and other branches of the fifth pair of nerves by means of repeated blisterings over the eyebrows and temples. Should this fail, we must endeavour to excite the torpid organ by acting immediately on the ciliary nerves, any irritation of which is speedily propagated to the ophthalmic ganglion and the origin of the trigeminus. This is most effectually done by the application of stimulants to the cornea, and of these stimulants the nitrate of silver in substance is the best. The inferior segment of the cornea is to be lightly touched till we perceive a whitish cloud, the eye is then to be immediately washed with water. Considerable pain is felt, the whole apparatus of the eye is put into a state of such increased activity, that on the morrow a stranger might suppose that our patient laboured under acute ophthalmia. This treatment sometimes induces vomiting, and as it always occasions temporary contraction of the pupil, it must not be employed when there is a tendency to this evil. The operation requires to be repeated several times.—*Journ. Complem.*

Italian Medicine.

Induction of Premature Labour by a Sponge and by Puncture.—The first case was that of a woman in whom the pelvis was too small to permit the passage of a full grown child. Premature labour was induced in the eighth month. A plug of sponge an inch long, and of the size of a goose's

quill, was cautiously introduced into the cervix uteri and left there. In the course of three hours some short pains were felt, they alternately returned and disappeared till the evening, when the plug was withdrawn by the thread secured to it. The operation was repeated four times, and on the third evening labour regularly commenced. Both mother and child did well.

The second case was that of a young female aged seventeen, who was the victim of a very severe "eclampsia puerperarum," which threatened a fatal termination. Professor Lovati decided on bringing on premature labour, he punctured the membranes with a trocar, and discharged the liquor amnii. The labour did not commence till twenty-nine hours after the operation, and the patient ultimately recovered.

Remarks.—Professor Lovati generally prefers the employment of the sponge to puncturing the membranes, because the escape of the water before labour comes on, frequently renders that tedious and painful. He objects to the method of frictions over the uterus, of irritating the cervix uteri, and of separating the bag of membranes from its attachment round the cervix. He however admits, that in cases which require very prompt delivery, as in the second one reported above, we must resort to puncturing the membranes, as the use of the sponge is too tedious.

It is a singular fact that the inducement of premature labour is prohibited by law in France.—*Annal. Univ.*

Chloride of Lime as a Lotion against Itch.—Professor Fantonetti gives the result of nine trials. In seven of them the disease was cured in from six to eight days; in the eighth case the psorous eruption was removed, but was followed by an eczema, which gave way to the use of tepid baths, and he left the hospital well; the itch, however, reappeared, and then yielded only to the sulphurous fumigations. In the ninth, the psora

was cured, reappeared, was cured again, returned a third time, and was finally subdued by the sulphurous fumigations. The chloride of lime lotion is made by adding 3jss or 3ij of the chloride to Oj of water; it ought to be rubbed three or four times a day on the affected parts. A simple tepid bath is to be used every third day in order to soften the skin and clear it of any calcareous crusts. If the lotion is too irritating its strength must be reduced. The disease is generally cured effectually in eight days.—*Ibid.*

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Inguinal Abscess.

JAMES DUNCAN, ætat. four years, was admitted into the hospital last week under the care of Mr. Earle under the following circumstances. About two months ago the child fell from a chair with some violence on the ground, but appeared to have received no injurious effects from the accident, which merely caused it to cry a little for a few minutes. A few days after the accident, the mother of the child, when in the act of washing him, discovered a swelling in his groin of an oval shape. The child suffered no inconvenience from the tumour. The mother applied immediately for his admission into the hospital. On examination, we found the tumour to occupy a considerable surface of the inguinal portion of the abdomen. It was soft and yielding. Mr. Earle seemed to entertain some doubts as to the nature of the tumour, and imagined that there was a connexion between the swelling and the descending colon. Mr. Stanley was of opinion that the tumour had nothing whatever to do with the intestine, and urged, in favour of his opinion, that no alteration had been discovered in the size of the swelling when the child was under the influence of powerful cathartics. He recommended Mr.

Earle to puncture the tumour. Mr. Earle accordingly proceeded to puncture the tumour, and having made an incision about an inch in length with a common bleeding lancet, a copious stream of pure laudable pus was discharged. Upwards of a quart of pus being evacuated, simple dressings were placed on the incision. It seems satisfactorily proved by many facts, that the intestine is not concerned in this tumour.

Extensive Burn.

A very fine child, about five years of age, was brought to the hospital some days ago for a very extensive burn of the breast, arm, and face. About six months ago the child fell into the fire, and received a very extensive and deep burn on the above mentioned parts. Unfortunately no medical assistance was applied for, in consequence of which a false adhesion took place between the chin and breast. The mother of the child applied for his admission into the hospital, at a time when it is probable little can be done for him. The child presents a very unsightly and disgusting appearance. The free motion of his head is entirely prevented, and he is obliged to keep it constantly in a downward position. The burn on the arm is going on well; but Mr. Earle is of opinion that nothing can be done with the burn of the chin and breast, with a view to separate the false adhesions which have taken place between them.

ST. GEORGE'S HOSPITAL.

JOHN THOMPSON, whose case we gave in our last, (inguinal hernia unexpectedly reduced,) is going on exceedingly favourably. The intestine has not come down since Monday, August 12; his bowels are regular, and he has greatly improved in his looks. The truss has been put on, and he will be discharged in a day or two.

Femoral Hernia.

Elizabeth Chapman was brought to the hospital on Sunday, August 18,

labouring under femoral hernia. She had been in the hospital on a former occasion, at which time the hernia was reduced, and she was discharged with a truss, which she happened to remove last Sunday, when the intestine suddenly fell down and could not be reduced. On her admission into the hospital her pulse was 96.

On examining the seat of the hernia a fulness was discovered at the superior and inner part of the femoral sheaths, which disappeared on pressure. It had much the appearance of an enlarged inguinal gland. It dilated when the patient coughed, and became less apparent when she lay in a recumbent position. The taxis was resorted to without success, and every attempt was made at reduction. An enema was given without delay. As the patient seemed rapidly sinking, Mr. Keate was immediately sent for. On his arrival, he found it impossible to reduce the hernia, and gave it as his opinion that an operation must be resorted to immediately. Accordingly at half past three o'clock on Monday morning he proceeded to operate. Having divided the integuments and superficial fascia, he exposed the hernial sac, and having cut through the stricture, he gently pushed back the intestine. The wound being dressed, the patient was conveyed back to bed. Up to Wednesday, August 21st, she has gone on well; has had several alvine evacuations, and does not complain of much uneasiness.

Dislocation of the Hip.

A strong and healthy-looking man was brought into the hospital on Monday with a dislocation of the hip. He was thrown out of a chaise on the Friday previous, and was unable to rise after the accident. On examination, it was found that the head of the femur was thrown upwards and outwards upon the dorsum of the ilium. The limb on the injured side was about three inches shorter than the sound limb. The knee and foot were turned in an inward direction. The motion outwards was entirely destroyed. The head of the bone was

felt distinctly on the dorsum of the ilium when the knee was rotated inwards. The glutei muscles, as also the triceps, pectineus, rectus obturator externus, &c. were shortened.

The patient was put into a warm bath at the temperature of 100°, with a view to accelerate syncope. When he became faint he was enveloped in blankets and brought into the board room on a bed. Mr. Brodie proceeded to reduce the dislocation by extension with bandages. A strong linen sheet being securely tied round his thigh, Mr. Brodie directed three assistants to pull gently; three other assistants held the man's arms and breast. Mr. Brodie, himself holding the thigh, gave the signal to the assistants to pull, and directed the head of the femur gently into the acetabulum.

Mr. Brodie said, that in cases of recent dislocation he always employed extension with bandages in preference to extension by pulleys.

The reduction being accomplished, the patient was carefully removed to bed lest a further displacement might take place, from the very relaxed state of the muscles. The patient has been discharged perfectly cured.

French Hospital Reports.

HÔPITAL DES ENFANS MALADES.

Pleuro-pneumonia—Bleeding and revulsives—Cure—A boy, aged six years, was admitted on the 10th of January. From the report of his parents, it appeared that he had always enjoyed good health. Five days before his admission he was seized, without any known cause, with cough, general feeling of sickness, and want of appetite. On the following days the right side was seized with severe pain, increased cough, dyspnoea, vomiting after every fit of coughing, which prevented sleep.

11th. He was lying on his right side; complained of headach and dyspnoea, with a general feeling of *malaise*; pain occupying the anterior

portion of the left side of the chest, which was increased upon percussion, cough, or deep inspirations. In front of the chest respiration was free, and easy in each thoracic cavity; posteriorly and to the right side it was heavy and laboured. In the upper portion of the chest the *râle crepitant* was mingled with the bronchial respiration; cegophony was very manifest a little below the inferior angle of the scapula. The skin was hot; cough frequent, without expectoration; pulse 120, and quick; respiration 40; tongue slightly furred; nausea, without vomiting; pain in the stomach, with constipation, bowels having only acted once since the commencement of the malady. Syrup of mallows; mucilaginous julep; two scarifications on the right posterior surface of the chest; cataplasm over the stomach; half a lavement, with two spoonfuls of olive oil; low diet.

12th. Cough, dyspnœa, and pain in the side less; pulse 96; respiration 36; bowels freely opened; auscultation and percussion distinct; the same series of symptoms internally. A small blister was applied on the right posterior surface of the chest. In the evening the pulse rose to 101.

13th. Pulse 120; respiration 40; pain in the side slightly felt; acceleration of the pulse supposed to be caused by the blister, over which a poultice was placed.

14th. Pulse 96; respiration 30; bowels open daily; breathing obscure on the right side; voice firmer.

16th. Dyspnœa slightly increased; can lie easy on either side; stools natural; pulse 84; respiration, 32.

19th. Pulse risen to 120; respiration feeble on the right side; two scarifications.

On the 22nd he was quite well, and went home.

Entero-colitis and laryngitis—Treatment of the latter by friction with the croton tiglium oil—Death from tubercular peripneumony—Healthy state of the larynx.—Louis Lecomte, aged three years, admitted into the hospital January 18, has been

ill six weeks. Since the first coming on of the disease, there has been looseness of the bowels; evacuations generally yellow or green; pain and swelling in the stomach; slight cough.

19th. Tongue red at the edges; belly tense and painful on pressure; thin green evacuations during the night; skin hot and dry; pulse 100; cough frequent; respiration heard freely all over the chest. Syrup of gum; cataplasm over the belly; starch injection; low diet.

20th. Belly in same state; two green stools; pulse 120; respiration 36. Emollient bath; two leeches to the umbilicus.

24th. Cough worse; voice harsh; anterior part of the neck painful on pressure; no tumefaction; pulse 108; diarrhœa less. Poultice to the neck.

25th. Voice altered, harsh and weak; amygdalæ and pharynx covered with white mucous matter; cough and fever still continue. Two leeches to the sides of the larynx.

27th. Lowness and depression; pulse small and frequent; countenance anxious, and expressive of suffering; lips encrusted; tongue red and dry; diarrhœa complete; cegophony. Mallows; julep, with two drachms of syrup of poppies; lavement of poppy decoction; two more leeches to the neck. On the following day the tartar emetic ointment was rubbed on the neck but neither this nor the fresh application of leeches was productive of any advantage.

30. Friction with three drops of croton oil.

Feb. 1st. Friction repeated; voice returned.

6th. Intense dyspnœa; cough frequent; pulse small and frequent; *râle crepitant* posteriorly and on the right side; sound obscure; respiration short and hurried; diarrhœa increased: syrup of guaiacum; mucilaginous julep with syrup of poppies; two dry cupping glasses to the parts affected.

9th. Ulcerations around the leech bites from the croton oil; diarrhœa; tongue dry; dyspnœa; extreme emaciation; pulse small, 150; respiration

every where feeble. Death occurred two days afterwards.

Necropsy.—The meninges of the brain were healthy, about a spoonful of serum was found in each lateral ventricle; in the chest were found some old adhesions of the lower lobe of the right lung, which contained many incipient isolated tubercles; hepatisation and redness of the middle lobe, in which was a tubercle of the size of a filbert; inferior lobe of the left lung in the same state; many of the large bronchial glands were filled with tubercles; the mucous membrane of the larynx, trachea, and bronchiæ were perfectly healthy, showing no morbid alteration whatever, either in colour or consistence; the heart and pericardium were healthy; in the abdomen the mesenteric ganglions were found tuberculated; liver very large; mucous membrane of the stomach was healthy, that of the cæcum was reddened, whilst in the descending colon and rectum it was softened, and in the latter intestine it was reddened, there were isolated red and black follicles also seen, but no sub-mucous tubercles.

HÔPITAL DE LA PITIE.

Large cancer of the face—Operation.—A man was placed under the care of M. Lisfranc with this disease. It was caused by his stooping down with a pen in his mouth, in doing which the point entered some lines in depth into the internal surface of the right cheek. A tumour soon showed itself, which, after a time, enlarged, and then ulcerated, accompanied with severe itching and deep lancinating pains, and discharging a sanious, acrid, ichorous pus, accompanied with fœtor. Gradually the ulceration increased, the edges were everted, and appeared, as well as the centre, of a greyish black and livid colour. The pains were much increased, and the sub-cellular tissue was crossed by large injected veins. In performing the operation the ulcerated part was removed by one internal excision carried below the orbit, and down to the

labial commissure, and the other external one in nearly the same direction, and in this manner the two excisions were united at an acute angle, forming a triangular section. This part of the operation was soon performed, but the securing the vessels (twenty in number) occupied some time. The tissue of the gums, which furnished a large number of vessels, bled freely, which was, however, arrested by cold water. The edges of the wound were brought into apposition by the twisted suture supported by a bandage. The man did very well.

LATEST ARRANGEMENTS OF GOVERNMENT RESPECTING CHOLERA.

We have just heard from authority on which we can place the fullest reliance, that Government are at present collecting private information from authentic sources, respecting the average spread and mortality of the epidemic Cholera, and that no steps will be taken, and no plan acted upon until such information is obtained. It is probable that ultimately one or more inspecting medical officers will be appointed to those districts where the ravages of the disease are most felt, and they will report the healthy or unhealthy state of the district over which they are placed, to the Secretary of State for the Home Department.

OBITUARY.

DEATH OF DR. DARWALL.

Our readers will have seen by the public papers the death of this excellent physician, from wounding himself in the examination of a body after death. In Birmingham, where his professional talents were much valued, his loss will be deeply felt; for few have passed through the rugged career of professional life more blamelessly than did the lamented subject of this obituary notice.

CORRESPONDENTS.

Mr. Hewlett's letter is received.

A. B.—The first book which the worthy Professor of Zoology wrote was entitled "The Duties of a Lady's Maid."

The statement of the arrangements of King's College for the ensuing session, 1833-34, will be noticed in our next.

Dr. Sutton's communication has been received.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LI., DELIVERED FEB. 11, 1833.

GENTLEMEN,—On the subject of the separation of the bones of the pelvis from each other, I have little to observe. Of course, such an accident cannot happen without the application of immense mechanical force; indeed, you will hardly ever find that it does happen, except there be at the same time a fracture of some part of the pelvis. Thus there may be in front a fracture through the ramus of the ischium and pubis, and behind, a separation of the sacrum from the os innominatum. Now, a case of this description might, from its appearance, lead one to suppose, that there was a dislocation of the thigh bone; for the ilium might be drawn upwards, and then there would also be a shortening of the limb; such cases I know have occurred, been mistaken for the dislocation alluded to, and extension has been employed under that supposition. When there is a separation of the bones of the pelvis at their sacro-ischiatic symphysis, nothing effectual, I believe, can be done to restore them to their proper position; you cannot effect reduction; all that you can do, if the patient live for any length of time, is to employ antiphlogistic means, and enjoin perfect quietude. These cases are generally fatal; for the violence that has produced them must in all cases have been very great, such as to occasion serious injury of the contents of the pelvis or abdomen. I remember, however, that we had on the table, two or three weeks ago, a preparation, which showed that the patient from whom it was taken, had lived some considerable

time after a disjunction of the sacrum from the os innominatum, for a firm union had taken place between the bones in their new position.

I come now, gentlemen, to an important class of cases, viz.—

Dislocations of the hip.—The femur is liable to four dislocations, which are universally acknowledged to be capable of occurring. You will sometimes read of another form of the accident, but one which has not been seen by some of the most experienced surgeons of the present time. Those which are recognised by all surgeons are the following:—In the *first*, the head of the femur is thrown upon the dorsum of the ilium, above the acetabulum and a little behind it; this is by far the most common direction, in which the head of the femur is dislocated. The *next*, in order of frequency, is where the head of the thigh bone is thrown into the obturator foramen, or upon the obturator externus muscle, and the obturator ligament. In the *third* dislocation, the head of the femur is thrown inwards and upwards upon the horizontal branch of the os pubis; this, perhaps, is the next in the order of frequency. The last is where the head of the bone is thrown backwards into the sacro-ischiatic foramen, and is lodged on the pyramiformis muscle. And with respect to the case which is not universally acknowledged, the head of the femur is represented as taking a still lower position, namely, behind the tuberosity of the ischium downwards and backwards. I conceive that such a dislocation, however rare, is possible; for even those who doubt the possibility of it, caution us, that when we are reducing a dislocation on the obturator foramen, we are not to incline the limb too forward, lest the head of the bone should slip into that very position. Sir Astley Cooper, who never met with such a case, cautions us against making extension, for the reduction of the dislocation into the obturator foramen, with the limb raised too much in front of the axis of the body. If I remember right, a case of this description has been recorded within the last twelvemonth

VOL. IV.

K

by Mr. Keate of St. George's Hospital. I think, in this instance, the dislocation behind the tuberosity of the ischium was a secondary displacement. A gentleman fell into a ditch, with his horse upon him; he lay under the animal for some time; his thigh-bone was dislocated; and the head of it was found to have been forced secondarily behind the tuberosity of the ischium. However, many surgeons only admit the possibility of four dislocations of the thigh, and Delpsch is one of them.

Except where the capsular ligament is much relaxed by the effects of disease, there must always, in these dislocations of the thigh-bone, be a laceration of the capsular ligament. There are instances on record, of persons who could dislocate the thigh-bone spontaneously, and afterwards replace it without assistance. A gentleman, attending these lectures, knows a person so circumstanced, and related some of the particulars to me. I suppose that in these cases there must have been an unusual relaxation of the synovial membrane, a rupture of the ligamentum teres, and perhaps an imperfect state of the acetabulum. But such examples are very rare; Sir Astley Cooper mentions one instance; I have heard of other cases, but I never saw one myself. In most dislocations of the hip, the ligamentum teres is ruptured: now, you would suppose, from a mere anatomical consideration of the joint, that the head of the femur might be dislocated on the obturator foramen, without any rupture of the ligamentum teres; for as that ligament is fixed to the anterior inferior part of the acetabulum, it seems to be capable of allowing the head of the bone to pass out of the socket on that side; but it is a disputed point, whether a dislocation can take place here without a rupture of this ligament. Sir Astley Cooper says, that a dislocation downwards and forwards, or into the obturator foramen, cannot take place without the ligamentum teres being ruptured, and he details one or two dissections, which corroborate this assertion. On the other hand, Delpsch asserts, that the ligament is not always ruptured, and relates some cases, in which he found the ligamentum teres unbroken; at the same time, he admits that it is sometimes broken. Sir Astley Cooper is of opinion, that the ligamentum teres is always ruptured in a dislocation of the femur, and that, notwithstanding the fact, that in the dead subject, the head of the femur may be drawn out of the acetabulum, and placed upon the obturator foramen without the ligamentum teres being ruptured, yet that the accident cannot occur to a living person, except when his limb is in a state of abduction; and that in such position, the ligamentum teres is on the stretch, and, therefore, if the force applied go so far as to dislocate the joint, the ligamentum teres must give way first.

Symptoms.—Now, gentlemen, with regard to the symptoms of a dislocation of the head

of the femur upon the dorsum of the ilium, which is the first case in order of frequency: in the first place, as the head of the bone is carried upwards, there must be a shortening of the limb; and, as it is also thrown backwards and the trochanter forwards, there must be an inversion of the limb; the knees and toes will be turned inwards; the great toe considerably, so as to be placed on the instep of the opposite foot; the prominence of the trochanter will be diminished, which necessarily happens, because the neck of the thigh bone takes the direction of the side of the ilium; the trochanter is also nearer than natural to the crista of the ilium. The symptoms, then, are a shortening of the limb, an inversion of the foot and knee; the change in the position of the trochanter, namely, its proximity to the crista of the ilium being increased, and its own prominence diminished; these are strong characteristic symptoms of the dislocation upon the dorsum of the ilium, particularly when the position of the great toe is considered, which is invariably turned towards the tarsus or instep of the opposite foot.

This dislocation upon the dorsum of the ilium can only happen when the patient has the inferior extremity in front of the axis of the body, with the foot inclined inwards. While he is in this position, if any great force act on the foot or knee, it will tend to throw the head of the femur out of the acetabulum upon the dorsum of the ilium. Surgeons have been much perplexed to know why, in this case, the toe should always be inclined inwards; they inquire why the head of the femur should always be thrown backwards, and the trochanter forwards. In this country no explanation has been offered of the fact, or none that has been admitted as a good one. In France, what has been considered there as a satisfactory explanation of the fact, has been offered, and is the following: The lower and inner part of the capsular ligament, not being lacerated, keeps the great trochanter forward, and the head of the bone is therefore always directed backward. Whether this explanation be admissible or not, it is difficult to say; but in France they not only account for the position of the femur in this dislocation, but in all the others, in the same manner, namely, by the consideration of the way in which the remains of the lacerated capsular ligament act upon the great trochanter.

The next most frequent dislocation of the head of the femur is that in which it is thrown upon the obturator foramen, on the obturator externus muscle, and obturator ligament. Here one particular symptom is always noticed, viz., the body is inclined forward by the tension of the psoas magnus and iliacus internus muscles; the limb is lengthened from two to four inches; and the trochanter is separated further than natural from the crista of the ilium. With respect to the position of the foot in this dislocation, you will find contradictory statements. Sir Astley Cooper says, that the position of

the foot is very little to be depended upon, and that sometimes it is but trivially altered; though frequently turned a little inwards. Professor Delpech, who has paid considerable attention to this subject, states that the foot is generally turned outwards. Then the limb will be elongated, as I have said; and the position of the trochanter will be altered in the manner I have described. The trochanter should always be particularly attended to in this, and, indeed, in all the dislocations of the femur. Its situation and position with respect to the crista of the ilium is a point to be strictly looked after, and you know that in this instance the distance between the two is increased.

In the third case in order of frequency, the head of the bone is thrown upon the horizontal branch of the pubes, and you find the limb shortened and turned a little outwards; you may also feel the head of the femur forming a distinct prominence below Poupert's ligament, and to the outer side of the femoral vessels.

In the dislocation backwards the limb is turned inwards, but not in so great a degree as in the dislocation upon the dorsum of the ilium: there is also a slight shortening of the limb, for the natural position of the ischiatic notch is a little higher than that of the acetabulum. There is likewise a diminution in the projection of the trochanter, and the head of the bone may be felt in its unnatural situation on rotating the thigh inwards; but, in fat persons, it will scarcely be perceptible, though you may rotate the limb as far inwards as you can.

The particular direction, which the head of the bone takes in each variety of dislocation, is determined by the position of the limb at the moment when the force operates which occasions the displacement. Thus, there cannot be a dislocation into the sacro-ischiatic notch unless the lower extremity be, at the moment of the accident, elevated in front of the axis of the body, or the body bent forwards over the thigh, which is the same thing.

I will now, gentlemen, explain the principles of reduction applicable to dislocations of the femur, and perhaps I shall render things more intelligible by repeating to you the symptoms of each case as I go on. I should mention, that the dislocation upon the dorsum of the ilium being attended with a shortening of the limb, might be mistaken for a fracture of the upper part of the femur; but the discrimination between the two cases is easy, when it is recollected, that in ninety-nine cases out of a hundred, the toes are everted in the fracture, while in the dislocation upon the dorsum of the ilium they are always turned inward. Another difference is, that the limb is altogether less moveable, or more rigid, in the dislocation than in the fracture. Then, in a fracture, even if it be one of the neck of the femur, you may, on drawing the limb downwards, feel a crepitus, and on discontinuing the extension, the shortening of the limb will

immediately recur; so that he must be a very careless practitioner who would confound a dislocation upon the dorsum of the ilium with a fracture of the upper part of the femur.

In reducing dislocations of the femur, three grand, or leading principles must constantly be attended to; namely, counter-extension, extension, and the employment of the shaft of the bone, as a lever for reducing its head. These are the principles which are of the greatest consequence, as you will find, that you cannot fulfil the principle of relaxing the muscles in these cases, because the bone is actually fixed in a particular position. But, gentlemen, though you cannot avail yourselves of the principle of relaxing the most powerful muscles by position, it is in your power, when great difficulty is encountered, to weaken them in another way, that is, by bleeding the patient; and, indeed, it will mostly be necessary to do this pretty largely. You may also find it necessary, in some instances, to reduce the force of the muscular system by giving nauseating doses of tartarised antimony, by which means a temporary weakness and collapse will be produced, during which you will be enabled to overcome with facility the slight resistance of the muscles. These, then, are the principles, and the only principles upon which dislocations of the thigh are to be reduced.

Counter-extension is performed by fixing the pelvis, which is done by means of a girth passed between the scrotum and the upper part of the dislocated thigh, and fixed to a point directly opposite that towards which the extension is to be made. Extension is generally made in this country at the lower part of the femur; but abroad the lower part of the limb, or the ankle is preferred for this purpose, and thus a longer lever is gained. The length of the lever is indeed of great advantage, and hence I am not surprised, that the best French surgeons should adopt this method of making the extension. The pelvis then being fixed in the manner I have mentioned, by means of a girth or table-cloth, you are next to apply the extending means. Now, in whatever situation you make extension, you must always take care to apply something next the skin to prevent it from being chafed; therefore, if you make extension with a sheet, you must apply underneath it, a wet roller; if a pulley is used, there is an apparatus for the purpose, which is frequently lined with flannel.

Now, gentlemen, when the dislocation is upon the dorsum of the ilium, the direction of the extension must be obliquely across the other knee; and of course the counter-extension should be made towards some point precisely in the opposite direction. I may now mention the symptoms of this dislocation again; there is an inversion of the foot, so that the great toe rests upon the opposite instep; the limb is shortened from one inch and a half to two inches; the trochanter is approximated nearer than natural to the crista of the ilium,

and is rendered less prominent on account of the neck of the femur lying in the direction of the side of the ilium; the limb too cannot be moved away from its fellow; it may be bent in a slight degree, but it cannot be moved into the position of abduction. Suppose the counter-extending means to be properly fixed on the pelvis, you then buckle an apparatus of this kind round the limb (*showing it*), you next fix the pulley. It is usual, in reducing the dislocation upon the dorsum of the ilium, for the patient to be placed on his back, either on the floor, or on a four-post bedstead such as this before me. Then, if it be the right femur that is dislocated, extension must be made in a direction obliquely across the left knee, with the pulley attached to the left post at the foot of the bed; while the counter-extending means are applied to the pelvis, as already described, namely, between the scrotum and the dislocated thigh, and fastened to a point precisely opposite to that towards which the extension is to be made. Now, as the pulley is fixed high, in this instance, the counter-extending girth must be fixed lower down than the edge of the bedstead, as is illustrated in this engraving. As soon as the extension has been carried far enough for the apparatus to be tense, and the patient to feel the effect of the power employed, you should not go on increasing the force at random, but proceed very cautiously and slowly, lest mischief should result. It is best, as soon as the muscles are put on the stretch, to wait a little, and let them gradually fatigue themselves, until their power of resistance is lessened. In short, the principle is, not to relax the extending power, but to keep it up until the head of the femur has descended near the acetabulum; then, when it is low enough for the lever-like movement to operate efficiently, it is of no use to increase the extension any further. You are now to put in practice the principle of making the shaft of the bone a lever for the reduction of its own head, which is accomplished by taking hold of the lower part of the limb, and rotating it outwards. The head of the bone is thus inclined directly towards the acetabulum by the lever-like movement of the limb. But, supposing great difficulty were to be experienced in effecting the reduction in this way, you would then apply a napkin, or band, to the thigh below the groin, and draw the upper part of the femur outwards with it, at the moment that the limb is suddenly rotated outwards, and the foot carried a little across the other. The napkin acts as a fulcrum for the lever-like movement, and the reduction is readily effected. When the brim of the acetabulum is very high, and the patient particularly strong, immense difficulty may be encountered in the reduction, unless the band be applied round the thigh in the way I have mentioned. The principles, upon which this dislocation of the thigh-bone is reduced, are therefore very simple; they are only three, namely, counter-extension, extension, and the

employment of the shaft of the bone as a lever for reducing its head; the latter being performed by rotating the limb outwards, and inclining the ankle inwards, as soon as the extension has been carried far enough. This latter manœuvre will bring the head of the bone towards the acetabulum, but if unusual difficulty is experienced, a band should be applied round the upper part of the thigh, in order that this portion of the femur may be drawn outwards. Such a band is in fact a fulcrum to assist in the execution of the lever-like movement of the limb. By these means, gentlemen, the dislocation, if not of too long a standing, may always be reduced.

I come now to the reduction of the next most frequent form of dislocation of the femur; that in which the head of the bone is thrown upon the obturator foramen. The symptoms of this case are a lengthening of the limb from two to four inches; the feet and knees of the dislocated limb are widely separated from those of the opposite limb; in other words, the limb is always in the position of abduction; the body is bent forwards, which is reckoned one of the most invariable symptoms, and arises in consequence of tension of the *psaos magnus* and *iliacus internus* muscles; the position of the toes is not constantly the same. This, as I have said, is a symptom not to be depended upon; for sometimes, the toes are turned a little inwards, and sometimes a little outwards. I think, however, this subject of the position of the toes in the dislocation upon the obturator foramen, ought to be more particularly studied, and recorded, because, as I have already observed, many contradictory accounts of this part of the diagnosis are given, and Professor Delpech, so far from agreeing with Sir Astley Cooper, in this matter, represents the toes as being very much turned outwards in this dislocation. Sir Astley Cooper says, that the position of the toes is not to be depended upon, but, that they are generally turned a little inwards. In consequence of the *glutæi* muscles being on the stretch, the buttock is flattened; and in this, as well as in all the dislocations of the thigh, the prominence of the great trochanter is diminished. Now, gentlemen, you will recollect that the limb is in the state of abduction, and, consequently, if extension were made in the direction in which the limb is thrown, without taking some precautions to prevent the pelvis from being drawn to one side, this would inevitably happen. Therefore the common means of fixing the pelvis will not be sufficient; it will be necessary to put a girth or napkin round the pelvis, to counteract the tendency which the extension would have to carry it too far sideways. In the reduction of this dislocation, then, two means are made use of for the counter-extension, and without them the principle would not be conveniently fulfilled. The reduction of the dislocation on the obturator foramen is a most simple proceeding; in fact, as soon you have dislodged the

head of the bone from its situation, it will generally return of itself into its right place, on inclining the ankle or knee inwards. But if you cannot succeed by this plan, then you will be obliged to have recourse to the band round the thigh, in order to draw the upper part of the femur outwards, and thus you will have a fulcrum to promote the effect of the movement of the lower part of the limb inwards. In this manner you will succeed perfectly. There is one caution, however, to be observed in reducing a dislocation upon the obturator foramen, which is, to be careful, that while you are making the extension, the limb does not incline forward too much, otherwise the head of the bone may slip backward behind the tuberosity of the ischium, and thus constitute another form of dislocation, which is sometimes considered to be irreducible. Sir Astley Cooper states, that such a displacement could not be rectified, though I don't know upon what facts this view is founded; however, whether correct or not, we should wish to avoid the second kind of displacement at all events, and I therefore recommend you to recollect the caution given for the prevention of it.

Here, gentlemen, is a representation of the mode of reducing the dislocation upon the obturator foramen. You may observe the band, passed round the pelvis, to prevent the extension from carrying that part too much to one side; and here is the other counter-extending means, applied in the ordinary way, between the scrotum and the dislocated thigh. In this plate, the surgeon is represented as taking hold of the ankle, not for the purpose of performing extension, but of making the lever-like movement of the bone; but, you are not to suppose that no extension should be made. Certainly, this kind of dislocation does not require so much extension as that upon the dorsum of the ilium; yet a moderate degree of it is necessary.

In the dislocation into the sacro-ischiatic notch, the direction of the extension should be across the middle of the opposite thigh. The patient is most conveniently placed on his side, as shown in the drawing before us. This is a more difficult dislocation to reduce than that upon the dorsum of the ilium. Hence, you will generally find it necessary to apply the band round the upper part of the thigh, as a fulcrum, or rather as a means of raising the head of the bone over the brim of the acetabulum. At the period of attempting this, you should also give the lower part of the limb a twist outwards, by which movement the head of the bone will be inclined towards the acetabulum, with all the force of a long and considerable lever.

In the dislocation on the horizontal branch of the os pubis, the patient is also to be placed on his side; the pelvis is to be fixed with the common apparatus, and a band applied round the upper part of the thigh for the purpose of raising the head of the bone over the brim of

the acetabulum. The direction of the extension ought to be in a line rather behind the axis of the body, and, as soon as the head of the bone has been drawn low enough for the lever-like movement to be put in practice, then the extension should cease, or, at all events, not be increased. The usual means are now to be put in force for completing the reduction, namely, the lever-like movement of the limb, and the use of the band round the upper part of the thigh as a fulcrum. In short, all dislocations of the thigh are reduced on the same principles; and whoever understands these well and scientifically can never be at a loss. Relaxation of the muscles cannot be accomplished by position, though it may be so by the effect of bleeding and nauseating doses of tartarised antimony. In many cases, indeed, and especially in those of long standing, such means become important auxiliaries, without which there would be no chance of success.

LECTURE LII., DELIVERED FEB. 13, 1833.

GENTLEMEN,—In the lecture delivered on Monday evening, I explained that the thigh bone is liable to four dislocations. The most frequent case is that upwards, in which the head of the femur lies under the glutæus minimus muscle upon the dorsum of the ilium, with the trochanter forwards. The symptoms are, a shortening of the limb, from an inch and a half to two inches; an inversion of the foot and knee; the great toe pointing towards the tarsus of the other foot; and as the head of the bone may be plainly felt on the dorsum of the ilium, there can be no difficulty in making out the nature of the accident. Then, the second dislocation of the femur is that upon the obturator foramen, or foramen ovale, in which the head of the bone lies upon the obturator externus muscle and ligament. In this case, the limb is lengthened from two to four inches; the position of the toes is not to be depended upon, for, in some cases, they are turned considerably outwards, while in others, they are inclined a little inwards. You may distinctly feel the head of the femur in its new situation, so that no great difficulty can occur in making out such a case. In this dislocation, two other very prominent symptoms present themselves; first, abduction of the limb, and secondly, an inclination of the body forwards, in consequence of the tension of the psoas magnus and iliacus internus muscle. In the third dislocation, the head of the femur is thrown upon the horizontal branch of the os pubis, on the outside of the femoral artery; and of course may be plainly felt in this situation; the limb is considerably everted; and, be it remembered, that this is the only dislocation of the thigh in which such eversion is invariably present; or, at all events, the only common dislocation; for, in the dislocation downwards and backwards, in which the head of the femur is thrown behind the tuberosity of the ischium, it is alleged that the toes are,

turned considerably outwards. Then, the fourth dislocation is into the ischiatic notch, in which the head of the bone is lodged upon the pyriformis muscle: here the great toe is turned inwards, but not so much as in the dislocation upon the dorsum of the ilium, and, instead of being directed to the tarsus, it is merely turned towards the ball of the great toe of the opposite foot.

Gentlemen, I mentioned to you, in the last lecture, the possibility of the dislocation downwards and backwards, in which the head of the thigh bone is absolutely thrown behind the tuberosity of the ischium. Such a case presented itself last February in the practice of Mr. Keate; the patient being a gentleman, whose horse fell with him into a ditch. It appears that the animal lay upon him for some time—for five or ten minutes—during which he continued struggling to liberate himself from his painful situation as well as he could. From the particulars, as related in the Medical Gazette, it seems that the original dislocation was upon the obturator foramen, but by a secondary displacement, which occurred during the patient's struggles, the head of the bone was thrown behind the tuberosity of the ischium, the very situation from which Sir Astley Cooper considers that the reduction would be impracticable. However, in this case, the reduction was really attended with no very great difficulty; the bone was first replaced upon the obturator foramen, and afterwards, by pursuing the plans proper for reduction of the dislocation on the obturator foramen, the head of the bone was replaced with tolerable facility. In this instance, there was abduction of the limb, and the head of the bone could be plainly felt behind the tuberosity of the ischium; the toes were also turned considerably outwards. If there be no mistake in the account, the case proves, in the first place, the possibility of such a dislocation, and secondly, so far from its being irremediable, that there is no very great difficulty in effecting the reduction. We also find an enumeration of the symptoms, namely, a lengthening and an abduction of the limb, eversion of the toes, and the being able to feel the head of the bone in its unnatural situation. It is worth your while, gentlemen, to remember, that this dislocation, though rare, may be met with.

These drawings represent the position of the limb in the dislocations upon the dorsum of the ilium, and upon the obturator foramen. You will observe, that, in the latter, the limb is represented as everted.

Dislocations of the patella.—The patella, gentlemen, is liable to three dislocations; first, outwards on the external condyle; secondly, inwards on the internal condyle; and lastly, upwards, when the ligamentum patellæ has been ruptured, which sometimes happens. There are also some other modes of displacement, for occasionally the patella is simply twisted, with the inner edge forwards and the

external one backwards, so as to form a considerable projection on the front of the knee; and sometimes it is thrown on the external condyle and twisted round. But the most frequent form of displacement of the patella is, where it is thrown flat upon the external condyle. This dislocation is most frequently seen in those persons, whose knees are considerably inclined inwards. In persons of this conformation, you may easily conceive how the action of the extensors of the leg may draw the bone outwards. When persons are knock-kneed, as it is called, and the ligament of the patella particularly loose, this dislocation is very apt to take place, the action of the extensors of the leg being often sufficient to produce it, without the aid of external violence. I mentioned, a few evenings ago, the case of a young girl brought up to tumbling, in whom the ligaments of the knee-joint and patella were so loose, in each limb, that both patellæ slipped to the outer side of the external condyle of the femur, whenever the extensors acted. The dislocation inwards, however, is generally produced by external violence, or a blow on the external edge of the patella, by which it is driven inwards. Both these dislocations are reduced on the same principles, namely, relaxation of the extensors of the leg, by bringing the knee as near as possible to the ilium, and then pressing the displaced bone outwards or inwards, according to the direction of the displacement. There is generally no great difficulty in effecting the reduction. However, instances are known in which considerable difficulty was experienced; and such an instance occurred to Mr. George Young, who found, however, that by placing the patient's foot against his own shoulder, and pressing on the patella with both hands, while the limb was in this position, the reduction became very practicable, though the ordinary method failed. I should mention, that owing to the looseness of the ligaments in certain individuals, and an extraordinary obliquity of the articular surface of the lower end of the femur, it is sometimes difficult to maintain the reduction after it has been accomplished, and therefore it becomes necessary to apply a roller over the patella, in the figure of 8 manner, to keep it steady, and in its place. If there be much swelling, the roller should not be applied until the inflammation has been lessened by cold lotions, purgatives, leeches, &c.

When the dislocation takes place upwards, in consequence of a rupture of the ligamentum patellæ, there is generally a vast degree of swelling about the joint, for this dislocation can only be produced by great and direct violence, by which the capsular ligament is also torn, so that a severe degree of inflammation commonly follows. Here also the principle of relaxing the extensors of the leg should be observed, by placing the limb on an oblique plane, extending from the tuberosity of the ischium to the heel. You will not be able to

apply a bandage at first; but after three or four days, when the inflammation and swelling are diminished, a roller should be put round the lower part of the thigh, so as to confine the patella as near as possible to the tibia. After about three weeks, it is advisable in these cases to have recourse to passive motion of the joint; that is, a person must be directed to bend and extend it a little every day, for the purpose of preventing the risk of ankylosis.

I observe, that a case is related in the last number of the Medical Gazette, in which the patella was not only thrown outwards upon the external condyle, but twisted so that the front surface of the bone was turned backwards, and its posterior surface forwards; but such an accident is far less common than the simple dislocation outwards.

Dislocations of the knee.—The knee-joint, gentlemen, as you well know, does not derive much strength from the conformation of the bones; but it is rendered immensely strong by the number, the strength, and the arrangement of its ligaments; so strong, indeed, that dislocations of this joint are as rare as those of any other joint of the body; at all events, no other joint, equally exposed to external violence, is so seldom dislocated. However, you will meet with dislocations of the knee-joint, which may take place in four directions; the head of the tibia may be displaced inwards or outwards, but when the dislocation is in either of these directions, it is always incomplete, and the accident is exceedingly rare. Lateral dislocations of the knee-joint are more uncommon than those in which the head of the tibia is thrown either backwards or forwards. There was a case in Guy's Hospital some years ago, in which the tibia was dislocated backwards, and the condyles of the femur displaced forwards, and in that case there was such pressure on the popliteal artery by the displaced tibia, that the pulsation in the anterior tibial artery at the instep was stopped. All dislocations of the knee are exceedingly rare, yet you will occasionally read of them; perhaps, in the course of twenty or thirty years, there may be one case brought into a large hospital. There can be no difficulty in recognising the nature of these cases, for the projection of the tibia and femur will render them sufficiently obvious. When the tibia is dislocated forwards, there is generally some laceration of the gastrocnemius and popliteus muscles. Sir Astley Cooper met with a case of incomplete dislocation of the knee-joint, in which the external condyle was thrown off the head of the tibia forwards, and the internal condyle backwards, and in this case, he found that there was no laceration of the crucial ligament; but if the tibia be completely dislocated backwards, then the crucial ligament, the lateral ligaments, and the muscles I have mentioned, are lacerated.

The principles of reduction in these cases, consist in bending the knee, so as to relax the strong muscles of the calf; and while the

femur is fixed, in making extension and pressing the head of the tibia in the proper direction.

Gentlemen, these dislocations, as I already observed to you, are rare cases; I have never seen one myself, and Sir Astley Cooper, whose experience is immense, has recorded but very few examples of them in his work on the present subject.

There is another form of dislocation of the knee-joint, which it is necessary to mention, namely, the dislocation of the condyles of the femur from the semilunar cartilages. It sometimes happens that the ligamentous bands, which fix the semilunar cartilages in their natural situation, become more elongated and relaxed than usual; now, this is particularly liable to be the case, when there is a collection of fluid in the joint, and under these circumstances, if the person in walking, happens to bring his foot in contact with any obstacle, one or both condyles of the femur may be dislocated off the corresponding semilunar cartilage, or cartilages; the result is, that the patient cannot straighten his leg, this is one of the symptoms; another is, a sudden attack of severe pain in the joint at the time the accident happens. Now the plan, adopted with success in these cases by Mr. Hey, consists in forcibly extending the limb, and then bending it as far as possible; this plan has succeeded, and I have tried it with success myself. In some cases, it will not answer, and then other plans may be tried. One of these consists in bending the thigh, and twisting the leg suddenly outwards; this plan has occasionally had the desired effect. Sir Astley Cooper, I think, mentions the case of a patient, who could never get the condyles replaced upon the semilunar cartilages, unless he followed this plan; he used to put himself on the floor, and then, by bending his thigh, and twisting his leg outwards, he was always able to accomplish the reduction, and procure instant relief. You will find that, when once this accident has happened, it will be liable to recur ever afterwards; on this account it is frequently prudent that the patient should wear a laced knee cap, so as to keep the knee steady and afford support to the joint.

Dislocation of the Fibula. The upper head of the fibula, gentlemen, is rarely dislocated by external violence; I have never seen a case thus produced; but you will occasionally meet with a dislocation of the upper head of the fibula in consequence of disease, and then it is thrown backwards. This is not a common case. The treatment consists in the employment of such remedies, as are calculated to stop the morbid process going on in the joint, which is generally of a scrofulous nature; you will be obliged to blister the part, and when you have stopped the further progress of the disease, you should perhaps employ compression to fix the head of the fibula in its proper place.

Dislocation of the ankle joint. The ankle joint, gentlemen, is frequently dislocated. The tibia may be dislocated off the astragalus in four directions. The most frequent case is that where the tibia is dislocated inwards, the tarsus being forced outwards; in this incident, there is a fracture of the fibula about two inches and a half or three inches above the malleolus externus, or the lower end of the bone; when the tibia is forced inwards off its articulation with the astragalus, the fibula mostly gives way at its slenderest part, which is at the point I have mentioned. In this case, there will be a considerable projection of the malleolus externus, rendering the integuments over it exceedingly tense; the broken part of the fibula inclines inwards towards the tibia; the position of the foot is strangely altered, its outer edge inclines upwards while its inner edge is turned downwards, so as to come in contact with the ground. When the accident has been caused by great violence, that portion of the tibia which is bound by ligament to the fibula is split off, and remains connected to the broken part of the latter bone, the ligament binding the fibula to the tibia in this situation being so strong, that a portion of the tibia splits off, before the ligament gives way. The nature of the case will be sufficiently obvious, from the projection of the tibia inwards, and the twisting of the foot in such a way, that the inner edge of it alone comes in contact with the ground when the patient attempts to walk.

There are two methods of treating this dislocation; though the plans of reduction approved of by all surgeons are the same; namely, you are to relax the strong muscles of the calf, this is an invariable principle, and then by making the requisite counter-extension, and practising extension from the end of the foot, the tibia may be easily replaced. But, whether the leg should remain in the bent position, or should be kept extended, after the reduction has been effected, seems to be a point, on which some of the most experienced surgeons differ. Sir Astley Cooper is an advocate for the straight position of the leg, and for the application of lateral splints, each having a foot piece attached to it, in order to prevent the foot from moving to either side. On the contrary, Baron Dupuytren adopts another plan; you know that the foot is displaced outwards; well, he first applies a thick wedge-shaped cushion at the lower part of the inside of the leg, with the thick end downwards, and over that he applies a long splint; the wedge-shaped cushion is to fill up the space between the inner edge of the foot and the splint, which must extend some way beyond the foot. Having secured the splint with a roller above, he next applies a bandage below in the form of the figure of 8, and thus draws the foot inwards towards the splint, which serves as a convenient fixed point. This engraving represents the appearance of the limb, in the dislocation of the tibia inwards.

The other lateral dislocation of the ankle joint is where the tibia is thrown off the astragalus, in the direction outwards. This is a rarer accident than the former; in fact, it cannot happen without the application of immense force; and, when it does take place, there is generally, or I may say always, a fracture of the tibia attending it, as well as of the fibula, a portion of the tibia being split off. Here is a representation of such a dislocation, taken from one of the preparations in the museum of St. Thomas's Hospital; a portion of the tibia, as you see, is broken off, and there is also a fracture of the fibula. This case is more uncommon than the other; for it requires the application of greater force; but a violent twist of the foot inwards may produce it. In this dislocation the position of the foot is the reverse of what it is in the case which we have been considering; you will find that it is the outer edge of the foot which comes in contact with the ground, while the inner edge is thrown inwards and upwards. The reduction is effected on the same principles, as in the dislocation of the tibia inwards, and therefore comprises relaxation of the strong muscles of the calf, counter-extension and extension; I may add, that there is no great difficulty in effecting the reduction. Sir Astley Cooper adopts the same method of treatment in this as in the dislocation of the tibia from the astragalus inwards; he puts the leg in the extended position, and applies lateral splints with foot pieces. Baron Dupuytren also adopts the plan, which I have mentioned as his practice in the dislocation of the tibia inwards, but he puts the wedge-shaped pad and the long splint on the outside of the leg, for here the object is to bind the foot in this direction. In the third dislocation of the ankle-joint, the lower head of the tibia is thrown off the astragalus forwards upon the os naviculare; you will therefore notice a lengthening of the heel and shortening of the foot. The dislocation may be either complete or incomplete; the tibia may be thrown either off the astragalus altogether, or only partially, half of it resting upon that bone, and half upon the os naviculare. In the latter case, the shortening of the foot may be very inconsiderable, and scarcely noticed by a careless practitioner.

The fourth dislocation is exceedingly rare; some of the most experienced surgeons have never seen it; I mean the accident in which the head of the tibia is thrown off the astragalus backwards, with immense elongation of the foot and shortening of the heel. This case is so rare, that Sir Astley Cooper gives us no instance of it in his valuable work, and Baron Dupuytren has never met with an example of it: consequently, it must be quite unnecessary for me to waste your time on what cannot be interesting to practical surgeons.

Another more interesting kind of dislocation to you is that of the astragalus itself forwards from the os naviculare and os calcis, so as to

form a considerable projection on the instep. This is not a very common accident, but it sometimes happens. I have seen not less than three examples of it. The dislocation may be either complete or incomplete. The reduction is sometimes exceedingly difficult, and when it cannot be effected, the accident is a serious one, for the patient is never afterwards able to put his heel to the ground, and his ankle remains permanently stiff. I remember being called in to a lady in Hunter-street, who had met with this accident two or three weeks before I saw her. Reduction was quite impossible; she was a fat woman, and the injury was attended with so much swelling at first, that the surgeon who saw her directly after the occurrence of the accident, could not make out the case. I perceived that it was a dislocation of the astragalus, and reduction being impracticable, she remains lame, with a stiff ankle joint.

In consequence of this dislocation being sometimes irreducible, even under the most skilful treatment, it has been proposed, when reduction cannot be effected, to cut away the astragalus altogether. This has sometimes been done, and when it is a case of compound dislocation of the ankle joint, accompanied by displacement of the astragalus, it may be the best practice to cut away the bone; but, in simple dislocations, I think, this proceeding would hardly be justifiable. Of course, in all cases you would first try to reduce the bone. The plan of reduction is to relax the muscles of the calf, extend the foot as much as possible, and then press the bone into its place. In some instances, as I have said, you will not succeed; and cases have happened, in which the skin covering the displaced bone has inflamed and sloughed, as you see represented in this plate, so that the bone is exposed. Sir Astley Cooper in the case I am now speaking of, divided the exposed ligamentous connections of the astragalus, and the bone came away; there was not so much weakness of the joint produced as might have been expected, and in eleven months, the gentleman who was the subject of the accident, was able to perform his duties as a cavalry officer, which implies a considerable power of using the joint.

I have now, gentlemen, delivered as much information on the subject of dislocations as can be done in this course of lectures: the subject is so endless, that it is impossible to follow it up with proper minuteness. However, I would particularly recommend you to improve the views which I have given, by the careful study of Sir Astley Cooper's work on dislocations, which is the most practical book on the subject. To complete your knowledge of dislocations, I would recommend you also to read Baron Dupuytren's numerous observations on the same topic; for he has paid great attention to this branch of surgery, as well as Sir Astley Cooper: they seem, indeed, to have chosen the same cases for their particular consideration. Now, as there are many

valuable practical observations in the lectures of the one, which are not contained in the publications of the other, while Sir Astley Cooper's work comprises numerous facts and reflections not to be found in the lectures of Baron Dupuytren, I recommend you to weigh attentively what each of these great and experienced surgeons has taught. Gentlemen, as this is the conversazione night, I will not detain you any longer.

CLINICAL LECTURES,

DELIVERED AT THE

HOTEL DIEU, IN PARIS,

During the Session of 1832-33.

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

Particular species of encysted fibro-cellular Tumours, better known as Ganglions or Nervous Tubercles.

EVERY accidental membranous production similar to a shut sac formed around any body, which, by some morbid process may be developed in its interior, is called a *cyst*. This species of morbid tissue may be separated into two great divisions, one comprising all those cysts which are organised around a foreign body, whether fluid or solid, the other including all those formed spontaneously, and which existed before the substances which they contain.

Effused blood, grains of lead, balls, urinary calculi, extra-uterine or ovarian foetuses, hydatids, &c.,—these are the substances around which cysts are usually formed. In the second division, including cysts spontaneously formed, and pre-existent to the substances which they contain, are included serous, synovial, melon-bodied, steatomatous, atheromatous, oily, mucous, and gelatiform cysts, and a small hydatiform tumour, well described by M. Dupuytren, and which has been hitherto only observed on the palmar surface of the wrist, though sometimes seen over the tibia-tarsal articulation, but always around synovial membranes and tendons.

In the third division, finally, are placed those fibrous productions which are characterised by a dense white resisting tissue, little extensive, generally disposed in lines, the greater number of which are contained in fibrous or fibro-cellular membranes. These latter have the greatest analogy with those small encysted tumours which we are now going to describe. By their nature, configuration, seat, and termination, they cannot be confounded with any of the preceding descriptions, for they are fibro-cellular in their structure, are nearly round in shape, never exceed the size of a pea, are generally seated beneath the skin in the direction of a limb, and which the eye has a difficulty in distinguishing, and they terminate in scirrhous ramollissement.

It is difficult at first to believe that such a small tumour can become the seat of such severe pain and suffering, and which eventually forms the point of fixture for one of the most serious lesions which can affect the animal economy.

Many authors have given a tolerably exact description of these tumours, but they have believed them to be situated in the nervous tissue, or specially in their course. Thus:—Antoine Petit, in his discourse upon Pain, after having stated that the minute ramifications of nerves are more sensible than the nervous trunks, says, “the nervous ganglions are but little known; they show themselves under the form of small bodies of the size of a bean, hard, moveable, colourless, frequently showing themselves in parts which have been struck, and sometimes occurring without any very evident cause, occasioning severe pain when touched in the slightest manner, or on the gentlest motion, or by change of weather. No topical application relieves them, extirpation only can effect a cure. The dissection of them discovers a white tubercle covered by a fibrous membrane, generally adherent to the skin, and mostly free in the cellular tissue, where it appears connected only to the nervous filaments, of which it is the centre. The greatest number on which I have operated have been in the legs, one only on the arm.

Cheselden, in the tenth edit. of his *Anatomy*, page 136, after describing the structure of the skin, adds, “I have seen, twice, under the cutaneous envelopment of the tibia, a small tumour of the size of a pea, extremely sensible and hard. In the two cases I allude to, the pain was so great as to lead to the belief that the tumours were cancerous, and they were only cured by extirpation. Camper, after Cheselden, in his work *Demonstratio Anatomico-Pathologica, liber primus*, p. 11, says that it is a common thing to observe small tubercles in the cutaneous nerves, which are true ganglions. Although they do not exceed the size of a pea, they yet cause the patient both by night and by day very severe pain; they do not yield to external remedies, and they must be removed with the scalpel. I have met with them frequently among males. Internally they are white, are as hard as cartilage, and are seated in the tunics of nerves.

M. Chaussier, in his *Synoptic Table of Neuralgia*, speaks thus:—“Tubercles or nervous ganglions are seldom larger than a bean, often smaller; they are oblong, hard, flattened, white, and cartilaginous, sometimes brown on their surface or their interior. Enveloped by a fibrous membrane, freely moveable in the cellular tissue, they only seem adherent by nervous filaments, the pain accompanying them is very great, more or less extended, and is renewed at longer or shorter intervals, by the pressure of the tumour, the motion of the part, and sometimes without any apparent cause. They are more frequently observed on the lower extremities, and have been seen on

the back. They are situated in the thickness of the skin and cellular tissue, and in the course of a nerve. The pains they cause, radiating from one common centre, extend to a longer or shorter distance, following the distribution and connexion of the affected nerve. Excision is the only remedy. Finally; in a dissertation on local nervous affections, read in 1822, before the Faculty of Medicine, in Paris, the author, in speaking of these small tumours, to which he gives the same name as English surgeons—*painful subcutaneous tubercles*—says of them,—“they are developed beneath the skin in general, surrounded by cellular tissue, and appearing only adherent by nervous filaments. At other times they are situated in the thickness of the nerve itself, of which the filaments surround it.”

Thus we see that these authors whose sentiments we have just quoted, speak of the nervous nature of these tumours, without supporting this opinion by any positive fact. Some report that after their extirpation, nervous filaments were detected on their surface, but they give no observation on the dissection of these parts. This *coup d'œil*, which we have just rapidly glanced over, will have been sufficient to convince you that the history of these nervous tumours is far from being completed. Numerous observations have proved to me that the nerves are not implicated in them. I have dissected many most minutely in the dead body, and in order that I might be the better assured of their nature, I have in extirpating them from those who possessed sufficient moral firmness, removed at the same time a sufficient quantity of cellular tissue and I have never seen nervous filaments adhering to their surface. Their tissue is evidently fibro-cellular, slightly albuminous, and in time becomes scirrhous.

These tumours most frequently have their situation on the sub-cutaneous or sub-aponeurotic cellular tissue, and may also be developed in other parts. I have observed them in the mammae. They present themselves of the size of a grain of wheat or coffee, or of a small pea, sometimes long, lenticular, flattened, never attaining a greater size than that of a small bean, their exterior surface is smooth and opaque, and they are hard in substance. If they fall from a height on an even and resisting surface, they will rebound. Their tissue is homogenous, their colour of a dull white, without any cavity or partition, of a fibrous, fibro-cartilaginous, or cartilaginous consistence. If the nail be indented in them, a slight crackling is heard; they are enveloped in a dense, opaque, fibro-cellular covering, forming a complete cyst, preventing any further growth or enlargement of the parts within, which may perhaps be the cause of the severe pain they give.

These tumours are never affected by inflammation, not even by redness. The cellular tissue environing them undergoes no alteration. The skin covering them is generally healthy,

without any adhesions in the greater number of cases, and preserving its colour, sometimes, however, it is altered, and becomes of a violet colour, adhering firmly to their surface, and rendering them immovable. Neither in their substance nor on their surface, are any nervous filaments, they are independent of these organs.

FIRST CASE.—A woman came to the Hospital, having complained for some years past of severe pains of the cheek, which had been treated as rheumatic, or as neuralgia of the sub-orbital nerve. Blisters, leeches, pills, bleeding, &c., were used, but they were of no effect. One of the medical men who was consulted convinced that the pains depended on an affection of the nerves, made a section of the sub-orbital nerve at the sub-orbital foramen. Instead of diminishing the pain, it became more intolerable, and was insupportable when first we saw the patient. In passing the fingers over the seat of pain, a small hard tumour could be felt, which was moveable beneath the skin, which was of its natural colour; pressure on it caused severe pain. I extirpated the tumour, and at the same instant the pain was subdued, and she has felt nothing of it since.

It is very evident that if in this case the tumour was dependent on a nervous filament of this branch of the fifth pair, the section of the nerve ought at the moment it was done to have given the patient relief, but it continued with the same severity, and was only subdued by the excision of the tumour.

It is very easy to remark that the descriptions, which authors have given of the early stage of scirrhus or cancer, are exactly similar to those of these tumours. M. Cruveilhier, in his *Pathological Anatomy*, in speaking of scirrhus, says that it is formed of a fibro-cellular tissue here and there albuminous. Finally, like scirrhus, these tumours become softened, in the great majority of cases they become painful, in others indolent.

SECOND CASE.—A woman, aged 70, had a small tubercle of the shape and size of a pea, flattened, seated superficially beneath the skin a little above the internal surface of the knee joint; it was circumscribed and very moveable, and the skin over it was not at all changed. This woman pretended that the pains which this small body caused her were extreme and rendered life a burden to her. She said that it was eighteen years since she had at first remarked it, and that its increase had since been very slow; that it had only caused her inconvenience for eighteen months; the tumour was removed, the pain disappeared, and has not returned since.

If this tumour had been formed on the course of a nerve, or in its substance, would it have remained insensible to pain for seventeen years. This fact is a very proper one to prove the justness of our position.

THIRD CASE.—A woman, aged 59, had a small tumour situated immediately beneath the skin on the anterior surface of the fore-arm in front of the radius, about three inches above the wrist. The tumour was about the size of a large pea, slightly moveable, hard to the touch, and extremely sensible. It gave the patient no pain except when pressed upon, in which case the pain extended from the tumour upwards towards the body, and not downwards towards the fingers. It had gradually increased in volume during seven years, and for one year it had remained stationary. It was extirpated by an incision made in its centre, and in its nature it was evidently encysted.

M. Dupuytren remarked that their slow and chronic progress might be explained by the natural hardness of their enveloping texture. Their tendency to become softened after having existed for some time, formed a new proof of their scirrhus nature. When they become changed in structure the disease is reproduced in the neighbouring lymphatic ganglions if they are extirpated. I removed one from the upper part of the arm, which was already softened, and after a certain space of time the glands in the axilla became enlarged, and the disease reappeared in them.

Age and sex appear to exercise some degree of influence on the development of these tumours. Women are more subject to them than men, and they are more commonly remarked between the ages of thirty-five and sixty years. Their appearance is generally attributed to blows or falls upon the parts where they are situated. In some cases they appear to arise from pricked wounds.

FOURTH CASE.—A shoemaker pricked his finger with his awl. Soon after the accident, he experienced severe pain, and gradually a tumour developed itself over the wounded part, and seven years afterwards the paroxysms of pain were more severe and acute. Caustic was applied in vain; extirpation afforded complete success, and the patient felt no further inconvenience from it. The tubercle was small, hard, and of a cartilaginous texture, and enclosed in a cyst. These tumours will sometimes develop themselves during a rheumatic affection, and disappear when the patient is relieved from those causes producing the principal malady.

FIFTH CASE.—A medical student slept in an alcove built in a damp wall. Soon after coming to the hospital he had an attack of arthritis in the great toe, and in a short time afterwards, a tumour developed itself under the skin, covering the saphenous vein and nerve; it was hard, of the size of a grain of wheat, and when touched caused pain almost similar to an electric shock. In the course of a few days he was cured of the local affection, as well as of the sub-cutaneous tubercle. The occasional cause of these tubercles is in general obscure, and in the

majority of cases it is difficult to ascribe them to any cause.

The encysted fibrous tumours generally show themselves on the limbs, more especially the inferior ones. They have been observed on the back, the scrotum, the face and the mammae. They are seldom united together, when there are many they are generally isolated from each other. The affected parts are in general painful for some time before any swelling is perceived. Soon, however, the slightest friction or pressure causes lancinating pains. At the end of a certain space of time, generally long, they are felt below the integuments, which they lift up, and then are easily perceived, are generally hard and moveable, and the slightest pressure upon them is insupportable to the patient, and in the greater number of cases the skin preserves its natural colour, and generally the pain comes on in regular accessions, sharp and lancinating, as in cancer; those caused by pressure are similar to an electric shock, and they extend, spreading far from the seat of the tumour, especially when they are situated near to a nervous trunk: otherwise the pain is continued, they leave the patient but little respite, there is loss of sleep, and the health alters rapidly. If they are seated on the lower limbs, they retard and prevent progression. There are some irritable subjects who during the paroxysms suffer from real convulsive spasms. I was consulted by a young woman, who had for some time been troubled by a small tubercle of the size of a pea, situated over the superior and posterior part of the thigh, and from which she had suffered most horrible pain from the time of its first appearance; the slightest pressure on it caused convulsions; it was removed, and all her pains immediately disappeared. In many cases they remain for a long period of time indolent even to pain. The pain produced by these fibro-cellular encysted tumours, invisible almost from their smallness, has been frequently confounded with that produced by rheumatic or neuralgic affections, and the patients have in consequence been submitted to leechings and blisterings, and other energetic means. Two women, of whose cases we shall afterwards treat, were leeches and blistered the whole extent of the limb, although the tumour could be plainly felt and seen.

In neuralgia the pains are severe, extending the whole length of the affected nerve, and returning by regular periods of accession every hour, day, or week, and pressure does not increase them. But those which arise from a fibro-cellular encysted tumour, do not come on in regular accessions; they are frequently continued, do not always extend in every direction, pressure increases them, and they never have an interval of many hours without tormenting them. The name of ganglion, which has been given to them, might cause them to be confounded with those tumours which are developed in the sheaths of the tendons about the wrist, and to which a similar name has

been given; but the indolent state of these latter ones, their seat, their mobility during muscular contraction, their immobility under the skin, the presence of a cavity lined by a synovial membrane and filled with a synovial fluid, are characteristic distinctions sufficient to prevent their being confounded together.

If the tumour is moveable, and the skin over it of a natural colour, if it is situated away from any important internal organ, as a blood vessel, or a considerable nerve; if, in a word, it is sub-cutaneous, the prognostic is favourable. If, on the contrary, it is immoveable, adhering to a violet-coloured skin over it, and it begins to soften, the prognostic is unfavourable; for in that case, if it is removed, the disease, as was remarked before, is re-produced in the neighbouring lymphatic glands, and the patient soon shows all the symptoms of a cancerous diathesis. Caustic, said M. Dupuytren, has been sometimes used to destroy these tumours, but they hasten the softening of them, and do not remove the disease. It is true, some rare cases seem to show the value of narcotics in these cases to those whom the idea of an instrument gives great terror. A woman aged sixty years had one of these tubercles over the internal and posterior part of the knee. Notwithstanding the severe pain she suffered, she never would consent to an operation for its removal; narcotics were applied for a long time over the seat of the tumour, and they relieved the pain, which never returned.

The most sure, prompt, and least painful means, continued M. Dupuytren, is to extirpate them. When they are very small, a slight longitudinal incision made over the surface they occupy will be sufficient; if they are larger, about the size of a large pea, an incision in the form of a T will be necessary. In both cases the tumour must be seized and divided from the cellular tissue which unites it to the surrounding parts by a bistoury; the edges of the wound are then brought together and kept in union by strapping.

If the skin covering the tumour adheres to it, and is of a bluish colour, it must be removed with it; if the tumour is already softened, it must not be touched.

SIXTH CASE.—Marie Hareny, journey-woman, married, aged 55, came to the Hotel Dieu to be cured of continued severe pains, which came on in regular exacerbations. She was of a good constitution, and the catamenia had ceased, and dated the origin of her illness eighteen months back, to being exposed to severe cold, and catching rheumatism. Every means had been employed without avail against these attacks of pain, which still continued, and were exasperated by any fatigue. They presented two distinct characters. First their continuation; second, the accessions recurring about four times in the twenty-four hours, and being prolonged from a few minutes to one hour. These causes of pain might be determined

by compression or by a blow on the tumour, which was situated on the upper and inner part of the thigh, and the pains were lancinating and numbing in the direction downwards to the knee. They were extremely severe, harassing the patient greatly, and seeming as though the pained parts were being torn away. M. Dupuytren removed the tumour by an incision in the form of a T, each branch incision being about one inch in length; the skin and cellular tissue were divided, and the tumour was found imbedded in the latter, and of a white colour, it was removed by a probe-pointed bistoury, the pains immediately ceased on its being removed, and the edges of the wound were brought together by strapping.

On examining it, it was found to be surrounded by cellular tissue in a normal state. It was about the size of a small filbert, spheroidal in shape; its colour of a dull white, it was elastic in structure, and showed no trace of red vessels; in its interior there was no cavity or thickened substance, and it was finally formed of a filious envelope, and of a fibro-cellular tissue, wherein fibre predominated. The after treatment presented nothing worthy of observation, the wound healed kindly, and she left the hospital quite cured.

SEVENTH CASE.—M. Dupuytren was consulted by an old military man for a small tumour situated on the outer and upper surface of the right leg. He could give no precise epoch of its origin, but he had for some months felt shooting pains in the part, and had felt a small hard substance, the pressure of which caused extreme pains, and which had increased so much as almost to bereave him of his senses. They occurred many times in the day at greater or lesser intervals, and they extended from the seat of pain to the neighbouring parts. These symptoms left no doubt as to the nature of the malady: it was a fibro-cellular tumour. Its situation, extent, and the severity of the pain upon pressure, were so many proofs in favour of this opinion. An incision was made over it, it was seized with the forceps and removed. Four days afterwards the wound healed and the man did well.

EIGHTH CASE.—Two years since, M. le docteur Maux was called by le docteur Audi-beck to a patient, who, for two years, had suffered most severe pains in the left thigh, leg, and knee. He had taken every remedy employed in rheumatic and neuralgic cases. M. Maux, taught by the experience of M. Dupuytren, examined the limb with great care. Under the skin of the internal surface of the left knee there was a small tumour of the size of a pea, movable, and giving great pain on pressure. A small incision was made over it, and it was removed. The patient was completely freed from all further inconvenience of pain afterwards. M. Dupuytren examined the tumour carefully, and found it to be formed, externally, of a fibro-cellular membrane, and inter-

nally, of a fibrous structure, disposed concentrically, and somewhat similar to the fibrous structures situated between the bodies of the vertebrae.

NINTH CASE.—Madame P. had felt for three years most severe pains in the right leg, recurring three or four times a-day, and frequently causing syncope by their violence. On examining her, M. Dupuytren found a small fibrous tumour of the size of a cherry-stone on the inferior and anterior portion of the leg over the spine of the tibia. An incision was made over it, and it was at once removed. It was of a fibrous nature, enveloped in a cellulose-fibrous cyst. From this time the pains ceased, a slight blush of erysipelas developed itself around the wound, which soon yielded under gentle laxatives. The patient was perfectly cured in ten days, and never afterwards suffered any pains.

PLAN OF A UNIVERSAL ASSOCIATION OF MEDICAL MEN IN THE UNITED KINGDOM OF GREAT BRITAIN.

BY ALEX. THOMSON, M.B. OF ST. JOHN'S CAMB.

“—— Qui rectè vivendi prorogat horam,
Rusticus expectat dum diffluat annis; ut ille
Labitur et labetur in omne volubilis ævum.”

OBJECTS PROPOSED TO BE ACCOMPLISHED BY
THE ADOPTION OF THE FOLLOWING PLAN.

To melt the profession into one harmonious mass.

To recognise, in the spirit of the times and of reason, the equality of all the members of the profession.

To do away with the system of centralising medical knowledge.

To furnish a stimulus to the members of the profession to keep up their knowledge, if not for their own mental satisfaction, for sustaining the contact with their fellows in examining.

To put an end to the public lies, introduced into the various systems of medical government.

To assure to the country that those passed, really possess substantially and practically the elements of their profession.

To repress effectually the tampering with the public health by quacks, allowed and winked at by the existing bodies.

To abolish the false system of certificates.

To destroy the monopoly of lea-
turedships.

To enforce a good, without vex-
atious, system of preliminary edu-
cation.

To prevent examiners unfit for the
office being elected or retained.

To protect the pupil from unfair
questions or captious treatment in the
examination.

To secure by a fine for rejection,
that no man shall present himself
without a proper quantity of ele-
mentary knowledge.

To stigmatise dishonourable and
recrudent conduct in the members.

To create a fund for the wants of
the society.

A. The Society to consist of

1. All members of the Colleges of
Physicians of London, Dublin, Edin-
burgh, and Glasgow.

2. All members of the Colleges of
Surgeons of London, Dublin, and
Edinburgh.

3. All members of the Apothe-
caries' Company of London.

4. Doctors and Bachelors of Phy-
sic of the Universities of Cambridge,
Oxford, Dublin, Edinburgh, Aber-
deen, Glasgow, and St. Andrews'.

5. Persons of whatever nation, and
however and wherever educated, who
may pass successfully through the
examination.

6. Themuseums, libraries, property,
and buildings of the medical part of
all these bodies to become common
property.

7. Forty-one examiners, under 60
years of age, to be elected by a simple
majority of all the members in each
of the three countries, England, Ire-
land, and Scotland, in order to com-
mence the operations of the Society.

8. Eleven of these examiners to be
chosen by simple majority, as the
first council for each of the countries,
from the examiners resident in the
metropolitan towns.

9. A president to be chosen by
simple majority of each council for
each of the countries.

B. The Members.

1. Members chosen by the ma-
jority out of five examiners.

2. Members equal in all their
rights and privileges.

3. Members deciding all questions
of government by secret ballot.

4. Members yielding to the de-
cisions in all cases of a simple ma-
jority.

5. Members chosen by the exa-
miners, cease to be so on the exa-
mination being found to be unfair.

6. Members eligible to the office
of examiners, after twenty-five years
of age.

7. Members expelled ipso facto,
upon conviction before any public
tribunal of perjury, or of any other
crime, or of having seduced the
daughter or wife of a patient.

8. Members paying to the general
fund an annual subscription of ten
shillings.

C. Membership.

1. Candidates for, to be upwards
of twenty years of age.

2. Candidates for, furnish no tes-
timonials of study or acquirement,
but in place of this,—

3. ——— give notice to
some one examiner, whether of their
own country or not, of their intention
to submit themselves to examination,
one month previously to the day on
which they wish to be examined.

4. Candidates for, deposit in the
hands of the examiner to whom they
apply, previously to drawing out from
the urn the names of the other four
examiners, the sum of forty pounds.

5. Candidates for, receive from the
examiner a receipt for the same.

6. Candidates for, draw from an
urn, into which the examiner has
placed the names of all the examiners
in the county in which he, the exa-
miner, resides, the names of four
examiners to complete the examining
committee.

7. Candidates for, retouch one half
of the sum deposited, in the event
only of their successfully passing their
examinations.

8. Candidates for, forfeit the sum deposited, if they do not present themselves on the appointed day for examination.

9. Candidates for, are obliged to answer no questions except upon the established points of the sciences and arts indicated in the next regulation.

10. Candidates for, are examined in, *Latin*.—Cicero de Oratore and Celsus.

Greek.—Herodotus, and the aphorisms of Hippocrates.

English composition.—On a medical subject, drawn from an urn, in which each of the five examiners had deposited one in a sealed envelope, by the candidate.

Logic.—Duncan's or Whateley's.

Geometry.—First six books of Euclid.

Algebra.—First part of.

Philosophy.—Locke on the Human Understanding.

Anatomy.—Descriptive, regional, general, developmental, morbid.

Pathology.—Internal, or nature of diseases; external, or surgery.

Physiology.—Magendie's; Bell on the Nerves.

Chemistry.—Elements of analytical, elements of synthetical.

Botany.—Elements of physiological, descriptive, medical.

Materia Medica.—Of the British Pharmacopœias alone.

Legal Medicine.—Toxicology, medical evidence, &c.

Midwifery.—Embryotomy; labour and its consequences.

Some one system of each selected by the London Council.

D. Examiners.

1. Examiners to be unlimited in number.

2. Examiners to be chosen from members by the majority out of five examiners.

3. Examiners to have no privileges over the members, save that of being eligible for the council.

4. Examiners to cease their functions after sixty years of age.

5. Examiners degraded to mem-

bers upon being convicted by any one of the councils of refusing, except in case of illness, to examine, and of partial or unfair conduct in the examinations.

6. Examiners to be paid for their journeys and loss of time by the body in general.

7. Examiners to meet for examination in an apartment open to all members of the profession.

8. Examiners to assemble for examination in the chief town of the county to which they belong.

9. Examiners are special or general; special for one or more sciences, general for the whole of them.

10. Examiners to examine whenever called upon, three weeks' previous notice having been given them.

11. Examiners five in number for each examination.

12. Examiners—three of the five are always general examiners.

13. Examiners to place the names, whenever applied to individually for examination, of all the examiners in the county in which they reside, each in a sealed packet, into an urn, and allow the candidate to draw out four to complete the committee of examiners.

14. Examiners susceptible of being refused to the number of three after the first drawing by the candidate.

15. Examiners when refused by the candidate, replaced by a second drawing from the same urn; the names of the refused examiners having been replaced in the urn.

16. Examiners to advertise the four examiners so chosen of the time, place, and object of their re-union, three weeks previously.

17. Examiners to refuse examination in the country, if there be not in it a sufficient number of examiners to constitute a committee.

18. Examiners to choose, in the committee for examination, one of their number for a presiding examiner, to direct the examinations and defend the person examined from vexatious and unfair treatment.

19. Examiners to demand from the

candidate for the membership, previously to his drawing the complement of the committee from the urn, a deposit of £40, and in the event of his success, return him immediately £20.

20. Examiners to demand from the candidate for the examinership, previously to his drawing from the urn the complement of the committee, the sum of £20 as a deposit, and in the event of his success, return him immediately £10.

21. Examiners to decide, by a simple majority, the acceptance or rejection of the candidate.

22. Examiners to transmit the funds received, with a written account of the result of the examination, to the Metropolitan Council.

23. Examiners to give to the successful candidate a certificate signed by the whole of them, of his success.

24. Examiners prohibited from putting any questions to candidates for the memberships, except on the established points of the science.

25. Examiners permitted to put any questions they may deem necessary on the sciences connected with medicine, to the candidates for the general examinership.

26. Examiners required to examine for the special examinership in the science or sciences only in which the candidate demands examination.

27. Examiners to conduct the anatomical and surgical examinations on the body.

28. Examiners to conduct the pathological examinations in an hospital or dispensary, in which there are at the time at least a hundred patients; the tickets in the former case being removed from the beds, and require the candidate to examine, diagnose, prognose, and prescribe for all the cases, or for such of them as the examiners shall think proper to select.

29. Examiners to conduct the chemical examinations by causing the candidate to compose and decompose all or any of the substances named in the British pharmacopœias, the materials being placed before them, and

by questioning generally on the elements of the science.

30. Examiners to conduct the botanical examinations by questions on the elements of physiological botany, and by causing the candidate to recognise by sight, or by examination with the aid of a general system, the plants of the British pharmacopœias.

E. Examinership.

1. Candidates for, to be at least twenty-five years of age.

2. Candidates for, to give notice to some one examiner of their intention to submit themselves for examination one month previously to the day on which they wish to be examined.

3. Candidates for, to produce the examiner to whom the notification is made, their certificate of age, and of membership.

4. Candidates for, to deposit in the hands of the examiner to whom they apply, the sum of twenty pounds, previously to drawing out from the urn the names of the four examiners to form the complement of the examining committee.

5. Candidates for, to receive from the examiner the receipt for the money.

6. Candidates for, to draw after having made the deposit from an urn into which the examiner has placed the names of all the examiners in the county in which he the examiner resides, the names of four examiners to complete the examining committee.

7. Candidates for, to retouch the half of the sum deposited in the event of their successfully passing their examinations.

8. Candidates for, to forfeit the sum deposited, if they do not present themselves on the day appointed for the examination.

9. Candidates for, to answer any questions, theoretical, practical, or positive, that may be put to them for the sciences in which they demand examination, if for specific examiners; in all the sciences connected with medicine, if for general examiners.

F. Councillors.

1. Councillors, to be eleven in number for the Metropolitan towns of each of the three kingdoms.

2. Councillors to be chosen by ballot and simple majority on the 1st of January every year.

3. Councillors to be elected by a simple majority of the examiners resident in the metropolis of each country.

4. Councillors to announce the day of election of the new Council in the public journals one month previously.

5. Councillors to choose, by simple majority, on the day of, and immediately after, their election, one of their own body as president for the year.

6. Councillors to assemble in an apartment open to all members of the profession.

7. Councillors to meet once a month for the despatch of regular business.

8. Councillors to meet also for the purpose of deliberation whenever there is any difference of opinion on points of government.

9. Councillors to be considered as honorary officers.

10. Councillors to be degraded, *ipso facto*, to examiners, when they refuse to meet, except in case of illness, after a notice of five days.

11. Councillors to be obliged to vote on all questions laid before them in Councils.

12. Councillors unable to change the principles of the Association without consulting, and receiving the assent in writing of, a simple majority of the members.

13. Councillors to confer, in reunion of the three kingdoms, and by simple majority, with the Government on all subjects connected with the profession.

14. Councillors of Dublin and Edinburgh subservient to the Council of London in all other circumstances.

15. Councillors to annul the election of a member, or of an examiner, on proof being laid before them of the elections having been unfairly or negligently conducted.

16. Councillors to conduct, and are responsible for, the affairs of the Society.

17. Councillors to determine the amount of fees to be paid to the examiners for the examinations.

18. Councillors to frame, and sustain to the level of the science, a common Pharmacopœia for the United Kingdoms.

19. Councillors to select the systems of elements in each of the branches of study, in which the examinations are to take place.

20. Councillors to take care of the museums and libraries, seeing that they are properly lighted, cleaned, and supplied.

21. Councillors to remove all obstacles to the study of the members, and of young men studying the profession.

G. President of the Association.

1. President to be considered an honorary officer.

2. President to be elected on 1st of January in each year.

3. President to be chosen from the Council by a simple majority of its members for each of the three kingdoms.

4. President is the depositary of the funds in London.

5. President disburses the funds under the approval of the Council.

6. President signs all obligations of the Society.

7. President calls all meetings of the Council.

8. President prosecutes, under pain of degradation to the rank of members, all persons exercising the arts of medicine or surgery, without the licence of the Association, and in its name.

9. President is degraded to the rank of member upon being convicted of unfair conduct by the Council, aided by the oldest on the list of Metropolitan examiners, who is to preside during the investigation of the charges.

10. President decides all questions of order in the meetings of the Council.

Reviews.

The Animal Kingdom, arranged according to the Organisation, serving as a foundation for the Natural History of Animals, and an Introduction to Comparative Anatomy. By BARON CUVIER, &c. &c. London, 1833. G. Henderson.

THE lovers of natural history have a vast source of knowledge thrown open to them by the publication before us, which renders the great production of the modern Aristotle accessible to English readers. The translation is accurate, and the work is published on such low terms that it must command a general circulation. It is to appear in monthly numbers to the amount of thirty-six, and its price thirty-six shillings, while that of the original with plates is as many pounds! We are surprised at the terms at which this splendid work is offered to the public, and we are convinced that it cannot fail to obtain extensive patronage. There are few subjects more interesting and amusing than the study of natural history, and here is the best work of reference and authority. We select the following extract to illustrate the style of the renowned author:—

“The birth of organised beings is, therefore, the greatest mystery of the organic economy and of all nature: we see them developed, but never being formed; nay more, all those whose origin we can trace, have at first been attached to a body similar in form to their own, but which was developed before them—in a word, to a *parent*. So long as the offspring has no independent existence, but participates in that of its parent, it is called a *germ*.

“The place to which the germ is attached, and the cause which detaches it, and gives it an independent life, vary; but this primitive adhesion to a similar being is a rule without exception. The separation of the germ is called *generation*.

“Every organised being reproduces

others that are similar to itself, otherwise, death being a necessary consequence of life, the species would become extinct.

“Organised beings have even the faculty of reproducing, in degrees varying with the species, particular parts of which they may have been deprived—this is called the *power of reproduction*.

“The development of organised beings is more or less rapid, and more or less extended, as circumstances are more or less favourable. Heat, the abundance and species of nutriment, with other causes, exercise great influence, and this influence may extend to the whole body in general, or to certain organs in particular: thence arises the impossibility of a perfect similitude between the offspring and parent.

“Differences of this kind, between organised beings, form what are termed *varieties*.

“There is no proof, that all the differences, which now distinguish organised beings, are such as may have been produced by circumstances. All that has been advanced upon this subject is hypothetical. Experience, on the contrary, appears to prove, that, in the actual state of the globe, varieties are confined within rather narrow limits, and go back as far as we may, we still find those limits the same.

“We are thus compelled to admit of certain forms, which, from the origin of things, have perpetuated themselves without exceeding these limits, and every being appertaining to one or other of these forms constitutes what is termed a *species*. *Varieties* are accidental subdivisions of species.

“Generation being the only means of ascertaining the limits to which varieties may extend, species should be defined—the *re-union of individuals descended one from the other, or from common parents, or from such as resemble them as strongly as they resemble each other*. But although this definition is strict, it will be seen that its application to particular in-

dividuals may be very difficult, where the necessary experiments have not been made.

"Thus then it stands—absorption, assimilation, exhalation, development, and generation, are functions common to all living bodies; birth and death the universal limits of their existence; an areolar, contractile tissue, containing within its laminæ fluids or gases in motion, the general essence of its structure; substances, almost all susceptible of conversion into fluids or gases, and combinations capable of an easy and mutual transformation, the basis of their chemical composition. Fixed forms that are perpetuated by generation distinguish their species, determine the complication of the secondary functions proper to each of them, and assign to them the parts they are to play on the great stage of the universe. These forms are neither produced nor changed by their own agency—life supposes their existence, its flame can only be kindled in an organisation already prepared, and the most profound meditation and lynx-eyed and delicate observation can penetrate no farther than the mystery of the pre-existence of germs."

Principles and Illustrations of Morbid Anatomy. By JOHN HOPE, M.D. Part VI. Whittaker.

IN looking for a few years back towards the low degraded state of medical literature, and comparing it with the high rank in science which any work issuing from the medical press now holds, we cannot help feeling astonished at the rapid strides which this literary department of our profession has made within a very recent epoch of time. The thirst for the acquirement of medical knowledge has been proportionate with the demands which disease, sickness, and suffering have made upon it; those internal morbid affections of the heart and other viscera, those chronic changes of structure affecting the in-

testinal and other mucous membranes, which but a few short years since were enveloped in such complicated mystery, are now rendered familiar to the youngest tyro by the splendid specimens of morbid anatomy in the museums of every hospital in London; nor are these the only fountains of pathological knowledge whence rich stores of learning in this branch of our profession may be gleaned; the medical press teems with works in every department of pathology, and morbid representations of scirrhus of the pylorus, or *ramollissement* of the spinal marrow, are as familiar as the structure of a fatty tumour or the eruptive appearance of the small-pox.

These remarks have been called forth by the examination of the valuable work on "*Morbid Anatomy*" now before us. The sixth part which we have more particularly under our notice, represents and speaks of those morbid changes which occur in the alimentary canal below the attachment of the diaphragm, including lesions, hyperæmia, and softening, and these are illustrated by the accompanying representations of changes of structure, made by the author from the diseased surfaces themselves.

Hyperæmia always supposes some degree of redness to pervade the mucous membrane, which has led into the double error of supposing it in some cases to be the natural appearance of the part, whilst in others it has been regarded as the result of inflammation; in order to avoid these two extremes of judgment the pathologist should be well acquainted with the natural appearance of a part, the proper performance of whose functions is so essential to the healthy action of this portion of the animal economy.

"The intestinal mucous membrane of a living animal, during a tranquil state of the circulation, is observed to be of a red tint, somewhat deeper than that of the mucous membrane of the cheek of a healthy man. This tint is replaced by uniform paleness, or at the utmost by a delicate

rosy tinge, when the animal is deprived of life without much loss of blood, which causes preternatural paleness, and without asphyxia, which causes mechanical injection. It thus appears that the mucous membrane, like the skin, tends to become pale after death. Accordingly, in the human species, as well as in animals, it has been found of this colour in most cases of accidental death occurring during a state of perfect health. The pale colour, however, is not of the same shades in all parts of the canal and at all ages. In the stomach, and still more in the great intestine of the adult, it presents a dead white hue, while in the duodenum and jejunum it is of an ashy or greyish white, which diminishes towards the end of the ilium.

"In the foetus and very young infants the membrane is tinged of a rose colour, which, gradually diminishing, is replaced in children by a milky and satiny whiteness, this becomes dimmer towards puberty, and in the adult passes into the ashy-grey shade above described. In the aged the grey colour becomes more decided and general, being in some measure dependent on the dilated and congested state of the sub-mucous veins, which impart a colour to the super-imposed membrane. In extreme old age, however, and in young children who have died of marasmus, the *maximum* degree of paleness is sometimes observed, being connected with the anæmia which exists under both these circumstances."

The performance of digestion, and the prevention of the return of the blood to the heart, will at all times occasion redness of the alimentary canal; after death, however, this state of parts may be referable only to two principal causes. 1. Gravitation of blood; and 2. Its transudation through the parietes of its vessels. In a diseased state of parts this redness may be reduced to four species, red, brown, slate-coloured, and black.

In the chapter on "Softening," the author in speaking of this morbid

change occurring in healthy parts, includes softening from putrefaction, and solution by the gastric juice; as connected with disease the mucous membrane alone may be affected, or the entire gastro-intestinal parietes may be involved.

The drawings accompanying the letter-press are well executed, and present some of the most faithful delineations of morbid structural changes which we have ever witnessed. We shall notice the ensuing numbers of the work as they appear.

A Treatise on Diseases of the Skin, founded on New Researches in Pathological Anatomy and Physiology. By P. RAYER, D. M. P. Translated from the French by W. B. Dickenson, Member of the Royal College of Surgeons. 8vo. pp. 400. London, 1833. John Churchill.

THE translation of M. Rayer has conferred a great obligation on the science of medicine in England, for the work is one which conveys to us not part merely, but the whole, of the information of our continental brethren on these difficult subjects.

M. Rayer had evidently bestowed great pains and industry in the observation of his cases, and much reflection and study in his deductions. Still the original work had been little circulated in this country, and its merits, but for the present translation, would have been perhaps but little known. Our countryman, Willan, appears to have preceded the French school by some years in the scientific investigation of cutaneous diseases, and his classification and arrangement founded on, and differing in no very material degree from, that of Plenck, has been adopted by M. Rayer, Alibert, and others, as the best at present existing. It is probable too, considering the difficulties which beset the subject, the constantly varying features of the different

diseases, their tendency to approximate each to the form of some other, and run from time to time through those changes which constitute pimple and vesicle, pustule, scall, scale, &c., it is the nearest to perfection we may be destined to see. Yet it is much to be wished it were more simple, for the divisions are so numerous, and the terms used so multiplied, as to make it a most discouraging task to attain a knowledge of them.

The descriptions of M. Rayer are remarkable for their correctness, and their value in diagnosis is, therefore, very great. Indeed, it is evident, that precision in this point is essential, and calculated to obviate much of the inconvenience above mentioned as regards the classification. The etiology of these diseases, he properly remarks, has been the subject of more hypothesis than positive research; their differential diagnosis has not been treated with the perspicuity desirable, and the therapeutic department has still many obscure points. This latter fact, he observes, is accounted for, inasmuch as there has been few experiments made in which the direct effect of the remedies has been clearly shown, their having been almost always limited to indicating the curative or distant effects. In fact, to announce that a patient affected by diabus, that is to say, acute or chronic inflammation of the skin, has been cured by dulcamara, rhus radicans, tincture of cantharides, or whey, or after having been bled once or oftener, and not to make known the form, extent, or degree of these inflammations of the skin, the state of the principal organs, and numerous other circumstances attendant on each individual case, is to publish a series of observations very nearly deprived of all interest. To say that such or such a remedy has sometimes succeeded, and that it has failed in cases exactly similar, without entering into the conditions which have influenced such opposite results, is to give us to

understand that chance presides over therapeutical experiments.

The capriciousness of these diseases, if we may use the term, however, constitutes, in our humble judgment, a very great obstacle to the due estimate of individual remedies or systems of management; for how often have we seen them obstinate and unyielding to all and every thing that theory can suggest, or empiricism itself hit upon, and yet vanishing spontaneously after the pursuit has been long given up in despair? In our opinion, when we consider the vast influence of mental and constitutional causes in the production of diseases of all tissues of the body made apparent to us, we are justified in thinking, that each of these are often operating unseen, and undisclosed, and unsuspected, and are therefore induced always to look with a more inquisitive eye into these points than at the disease of the surface. The influence of mental anxiety and distress is often so great as to produce the worst forms of lepra, and in these changing times it is not uncommon to see cause and effect clearly demonstrated. We remember a case a short time since of this kind, the patient was a stout-looking and rather corpulent man, a person whose appearance denoted what is termed good health. There was nothing tangible as explaining the cause of the disease. Every measure had been tried having a rational principle for its basis, when a crisis in his private affairs, which he had long dreaded and struggled to avert, arrived. His mind was relieved of its burthen, and he immediately recovered. Heberden, and later writers, considered lepra a rare disease in England; it is now, however, extremely common.

M. Rayer has culled with an unsparing hand from English authors, we are bound to say, in most instances, with due acknowledgments; but our readers have had these materials before them for some years. They comprehend a very valuable and very large part of the work, which con-

sidering its pretensions, and the probably grand object of the author of spreading the knowledge of cutaneous diseases on the continent, is no small praise. Continental authors have also furnished their quota of information, and the whole may be considered as a fair compilation of what has been published on these subjects up to the present time. The translation is, on the whole, creditably executed, though, we have no doubt, the author would have been better pleased, had it been accompanied by a copy of his illustrations.

We would not say anything against the book if we could, fearing to discourage the translation of scientific works in a country where every man's eyes are open from the highest to the lowest to the value of the propagation of knowledge. Its demerits are all of the negative kind; there certainly are deficiencies, but on the whole we think it our bounden duty to recommend our readers to place it on their shelves. What there is original in it may be read with advantage, and it will afterwards be found a useful book of reference.

ON THE USE OF THE CYNARA SCOLYMUS IN RHEUMATISM.

To the Editors of the *London Medical and Surgical Journal*.

GENTLEMEN,—Considering, as I do, that accumulation of facts as evidence is not barely useful but *essential*, in the establishment of the claim of any remedy, as efficacious in the relief of disease, I am happy in being able to add my testimony to that of Mr. Copeman, of the Norwich Hospital, in favour of the *cynara scolymus*, (the common artichoke,) in the treatment of rheumatism, and induced to forward to you reports of cases in which I have employed it with marked success.

The first case is of Elizabeth Harper, ætat. 75, a hale and strong woman, inhabiting a very exposed

situation. On June 10th complained of acute pain in both wrists, which on examination I found to be painful on being touched, and very much tumefied; bowels very regular, free from fever; pulse 80; tongue clean; pain aggravated at night. Gave the following mixture:—

R. *Succi cynaræ*, 3iv,
Syrup. simp. 3ij,
Aq. font. ad. 3vj.
M. Capiat partem iv am octavis horis.

11th. Pain much relieved; swellings slightly reduced; has passed a better night.—Continue medicine.

12th. Pain has ceased; swellings considerably less, and wrists no longer tender. A gentle aperient was to day necessary.—*Cont. Mist. Cynaræ.*

14th. Quite well. The wrists have regained their proper size, and the hands their use. This patient continued quite free from pain until the 3rd of this month (August), when she complained of pain in one shoulder, similar to what she had felt at the wrists, and begged that she might have some more of such medicine as she had had on the former occasion. It was immediately sent to her, and she was relieved as before.

SECOND CASE.—Mary Smith, ætat. 56, applied on July 16th for relief from severe pain in the loins, occurring soon after exposure to damp and cold. The pain was acute in the direction of the sciatic nerves of the left side, at times when the lumbago would be less distressing. On the preceding night had not slept, the pain being almost incessant. Tongue clean, and secretions regular; pulse 78. She being a younger woman, and more robust than Case 1st, I gave

R. *Succi Cynaræ*, 3vj, c.
Syrup. com. et aq. font. in formâ mixturæ, capiat ut supra.

17th. Pain has disappeared from the lumbar and sciatic regions by metastasis to the shoulders, which do not suffer so severely, but are very stiff. *Cont. med.*

18th. Better; shoulders less pain-

ful, but not less stiff; the bowels slightly confined; gave

Magnes. Sulph. 3iv.
in Aquâ font. 3xij.

19th. Draught operated satisfactorily, and pain considerably less. No second metastasis has taken place.

Cont. Mist. Cynaræ.

20th. The pain has ceased, and she can use the arms better; bowels regular.—*Perstet in usu Cynaræ.*

21st. Quite well; no pain, and the stiffness is now inappreciable. Up to the date of this communication this patient has continued well.

THIRD CASE.—July 19th. Henry Smith, husband of the above, ætat. 46, was attacked in a precisely similar way, the seat of pain in him being the lumbar region and knee of the left side; ordered him a mixture like his wife's.

20th. Metastasis to the right shoulder, yet with considerably less pain.—*Pergat.*

21. Pain has ceased, and not since returned.

FOURTH CASE.—Aug. 3rd. Samuel Fleur, ætat. 36, complains of considerable pain in his right shoulder which prevents his taking any rest at night, when it appears to be slightly aggravated. Bowels confined; pulse 90, and tongue white. Gave

R. Magnes. Sulph. ʒiiss.

Syrup. Sim. ʒss.

Aq. Ment. Pip. ad ʒvj. *M. Capiat coch iij mag. pro re natâ, secundis horis.*

4th. Bowels relieved soon after finishing the mixture; pain in the shoulder unabated, limb incapable of being moved from extreme pain and stiffness; pulse 80.

R. Succ. Cynaræ, ʒvj.

Aq. Ment. Pip. ʒvj. *M. Capiat part. iv am nocte maneque.*

5th. Relieved; pain in shoulder less; has slept for the first time for three nights.—*Perstet.*

7th. Gradually improving; bowels in good order; tongue clean, and pulse 70; shoulder less stiff.—*Perstet.*

12th. Is now so far recovered as to be able to go out to glean corn, and has discontinued medicine.

The foregoing I consider to be cases in which the efficacy of the medicine employed was very marked, and are the only ones of which I have preserved any notes. In more acute cases I have found the same medicine equally useful after bleeding, and in many cases where I had previously given the *Pulv. Ipec. c.*, antimonials, and the whole tribe of medicines usually esteemed in the treatment of this class of disease, without effect. I have never found it produce catharsis, as Mr. Copeman reports he has done*. The first hint which I received on the subject of the value of the *Cynara* in treating rheumatic affections, was from Mr. Johnson of Norwich, and for the first sample of a tincture prepared from it, I am indebted to Mr. Cooper, also of Norwich, two gentlemen indefatigable in the pursuits of science, and as eminently useful as esteemed in the practice of our profession.

The mode of making the preparation which I use being as simple as the remedy is useful, I will describe it, and recommend an inquiry for the leaves before they are destroyed for the season, and which has already been done in some gardens.

I use the juice only, which I extract by cutting the fibrous and fleshy portions of the leaf into short lengths, convenient for bruising in a marble mortar. The juice is then very easily separated from the pulp by pressure, and I find it keep very well by adding, after filtering, to every five ounces, one ounce of *spt. vin. rect.*

I am now in the daily habit of giving it, and have not yet employed it in any case in which it has not proved of service.

Finding this simple preparation so useful, I have not been induced to make either an extract or tincture. They are doubtless the most eligible

* Med. Gaz. vol. xi., page 844.

forms of preparation, more particularly for convenience, but scarcely likely to prove more efficacious, and are certainly in either process more expensive,

With sincerest respect, I remain

Your attached and constant reader,

JOHN JAMES HALLETT.

PROGRESS OF CHOLERA.

THE cholera is still very prevalent, and is not confined to the lower classes. It is much modified in its symptoms, when compared to those which characterised the disease last year. There is in general a premonitory diarrhoea, but the evacuations may be of varied appearance, rice-coloured, yellow, brown, and even black. We have seen a lady aged 76, who was seized with vomiting and diarrhoea at 7 o'clock in the morning, whose alvine discharges were black; we saw her at noon, and at the desire of her medical attendant used the saline transfusion, which did no good whatever, and she died in a few minutes afterwards: the skin of the face, hands, arms, legs, and feet being perfectly blue. We have seen two other blue cases since our last, in which the extremities were cold, pulse very weak, the tongue and the breath cold, the spasms in the abdomen and limbs violent; and all these symptoms were removed by strychnine, in the dose of one-twelfth of a grain every ten minutes. In the first

case, that of a strong woman, reaction took place as soon as twelve pills were taken, the pulse returned, voice became stronger, the countenance brightened, the vomiting, purging, and cramps ceased. The pills were continued every half hour afterwards, but collapse speedily ensued, and death occurred. In the second case of a delicate man who had been out of employment for three months, who eaten unripe apples the day preceding his attack, and was seized with all the symptoms of cholera at 10 o'clock on Saturday morning, his family did not discover his condition until 5 o'clock in the afternoon. He had vomiting, purging, cramps, with blueness of the face, hands, arms, and legs. He took eight strychnine pills from a quarter past five to half past six o'clock. His symptoms ceased, but he had no pulse. He continued the pills every half hour until one o'clock on Monday morning, when he expired. Reaction did not take place in this case, though heat, friction, &c. were sedulously employed. In several other cases life was saved by the strychnine in the first stage of the disease. In another case of a gentleman, ice was given by the mouth, cold water and broth injected by the rectum, and three drachms of calomel given before our arrival. Nevertheless the patient sunk. From all we have heard, read, and seen of the disease, we think strychnine is one of the best remedies when administered before collapse has commenced. We are convinced that it fails in the last stage of the disease, as all remedies

hitherto employed have repeatedly done.

As to the idea of the disease being contagious, we have held, since its appearance in this country, the opinion which was afterwards deliberately given by Magendie and all his fellow-countrymen, that it is **ABSURD**. We have sat upon the patients' beds for an hour at a time to dissipate the horrid notion entertained by relatives, that the disease was contagious, and then put this question to them:—"Do you suppose I should wish to communicate this frightful disease to my own family, or to any human being?" This was the *argumentum ad rem*—not the *argumentum ad absurdum* of the believers in contagion. Lastly; with respect to saline injections, we believe them, upon the whole, to be useless. They are founded upon the doctrine of Dr. Stevens, which every physiologist considers erroneous. Sanguineous transfusion, bears much more similitude to reason and science, and ought to be more extensively employed. We have heard of three cases only that were supposed to be cured by saline transfusion, but as many have been cured with cold water and various other remedies.

THE CORPSE OF THE CHOLERA
BILL.

WE promised in our last to lay before our readers any further account we might receive of this Bugaboo Bill. It has risen from the dead and come to life again, and has, moreover, been christened by the above name. The

ceremony of baptism was, however, but a very *blue* affair after all. The font was made of *blue-stone*, the clerk looked *blue*, the parson looked *blue*, the child, of course, was obliged to look *blue*, but a contemporary of ours, who officiated as god-father on the occasion, cut the poorest figure of all—he seemed fairly done *blue*. However, the prospect of the cholera child soon coming of age rallied his depressed spirits, and by his last pages we are glad to say he appears as frisky and foolish as ever.

After apostrophising SIR DAVID BARRY, and SIR WILLIAM RUSSELL, and apologising for his prematurely denouncing them as "*unprincipled*," he goes on with more eloquence than we had ever given him credit for, to describe himself and his similitude. "An editor of a medical journal," says he, "who is (*quære*, like myself) *literally stupid*, may be likened to a harnessed horse* which has the misfortune to fall prostrate in the mud. The miserable condition of the fallen animal excites the compassion of the friendly driver and all surrounding spectators. Every one in turn attempts to raise the fallen creature; and in turn every one receives a splash of mud-or a kick as a reward for his compassionate exertions†." We will be scotched if the Tom

* We understand that in the original MS. the word was written "*ass*," but the printer's devil, out of respect to his friend, wrote him down "a gentler animal."

† The latter portion of the above is a *travestie* sketch of what actually occurred when certain worthies and the police met in such *amicable* contact in the theatre of the College of Surgeons.

PAINÉ-BONE-MAN did not help our contemporary to concoct the above splendid specimen of pig-tail.

After this, however, he fairly breaks down; and when supporting the cholera contagion doctrine, he comports himself most marvellously like a merry-andrew, and like his friend, the horse, he kicks and splashes right and left. His doctrine is, "that one instance of indisputable contagion is sufficient to establish the whole doctrine of contagion;" for the premature delivery of which indisputable nonsense he is doubtless indebted to a pretty smart dose of ergot of rye. But we cannot afford space to follow this "*ignis fatuus*" any further. The truth is, that the "contagionists," with our contemporary at their head, the No-Bats, the Tittle-Bats, and the Anti-Bats, are in perfect ecstasies; they verily believe the Millennium is at hand; and it would be an act of real charity if the Commissioners of Lunacy would drop down upon them and send them all off to a mad-house.

We understand that the Editor of the *Cholera Gazette* has been sent for express from Paris, and is expected to arrive in a few days with a crew of Saint Simonians to undertake another *Cholera Gazette* "by authority." We here, however, beg to assure our worthy friend, that if we catch him "napping" any more, we may read him such a lesson as he never had read to him before; he shall eat his own words and swallow his own book.

THE Cholera and Irish Infirmary Bills passed on Wednesday night.

PERCUSSION IN CHOLERA.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—As some cases of cholera asphyxia have occurred to me in which a new mode of practice has been adopted, I request you to insert the results in your weekly Journal.

This practice was first begun in a case which appeared to have received no relief from the use of cold water plentifully allowed, with the addition of calomel in ten grain doses. It was the case of a boy of twelve years of age, who had been taken ill on the morning of the 28th of June. He had gruelly stools and no secretion of water, with cramps in the legs. He wished much to indulge in drinking cold water, in which he was encouraged. He took three doses of calomel of ten grains each, which, with a terebinthinate clyster, formed the treatment of the first twenty-four hours. The pulse was perceptible for the first twenty hours, during which time he had frequent colourless stools and vomitings. At eight o'clock on the second day, after a restless night, he was in a state of asphyxia. Extremities deadly cold; body in a state of complete torpor; stools and vomitings of the same character, but less frequent. He had, of his own accord, discontinued to drink cold water. In this state, when it was thought by Messrs. Hainson and Watsford, and myself, that the case had become one of extreme danger, it occurred to me to try the new remedy. Directions were given to percussate sharply with the hand on the right side in the region of the liver. This was done for nearly five hours. After the first hour the circulation in the face seemed to rouse; after the second, a slight pulsation was felt at the wrist, and in five hours, four of which had been employed in percussion, a black stool, with discharge of urine, took place, and the pulse was restored, and, in two hours more, two other black stools were voided. The next day, liquid coloured stools were passed, with the

natural appearance of bile in them. From this time the boy gradually recovered.

The next case of cholera asphyxia was in a patient of Mr. Smith's, of Deptford Bridge. On the previous day, costiveness and pain in the bowels were complained of, which were removed by a dose of calomel and aperients. On the second day the patient was found in a state of complete asphyxia, with gruelly stools, vomitings, severe cramps, and no discharge of urine. The case altogether appeared to him to be of the most serious character, and the friends were not inclined to disturb the patient by adopting those means of relief usually resorted to, thinking the case wholly hopeless. But Mr. Smith having had some conversation with me on the subject of percussion, determined to adopt it in this case, without the use of any other remedies. In five hours the patient appeared to be satisfactorily better in regard to circulation, and the percussion was continued two hours longer, when, in a short space of time, coloured stools came away, and the pulse was recovering itself, but no water was discharged until two days afterwards. The circumstance of the recovery of pulse, and the passing of coloured evacuations occurred a week since, but the non-evacuation of water no doubt kept up much irritation, the cause of which, from the first, seemed to be the want of power in the bladder to expel its contents. It now accumulates, and is drawn off twice or three times a-day. A degree of delirium still remains, with great restlessness, so that we cannot predict with certainty that he will recover.

The third case was in a woman aged 65. She had been taken with faintings and cholera asphyxia, seven hours before I saw her, accompanied with the usual stools and vomitings and want of urine. The surface of the body was cool, but the extremities and face were as cold as marble. A small dose of calomel was given, and friction and percussion were ordered to be used over the region of the

liver. This was assiduously done for five hours, at the end of which time the pulse at the wrist could be slightly felt, and some light bilious shreds appeared in the evacuations, and the face, with the exception of the nose, had lost somewhat of its marble coldness. The percussion was recommended to be persevered in during the night, which was attended to, to some extent. In eleven hours I again saw her; she had passed several stools, containing a considerable quantity of shreddy substance; the pulse had risen, and she was uniformly warm. For the next three days, I heard nothing of the case, until Mr. Jones, of Lewisham, who attended the patient, informed me, that after some hours, she had a free coloured evacuation from the bowels, with discharge of urine. The next day she took an opening draught, and appeared to be doing well.

As the treatment of this very fatal disease has led to no confidence in any one particular method, the above cases, though not numerous, may be worthy of attention. Sir William Pym, in a recent letter to me, says, that "all the remedies which were supposed to be successful last summer were afterwards found to fail."

I shall not at present go into a detail of my reasons for adopting the above method of treatment, but as I have related the results, the *modus operandi* may be perhaps sufficiently manifest. It may, however, be necessary for me to state, that in a case of cholera, where there was no loss of pulse nor deficient secretion of urine, the gruelly evacuations, after seven hours of friction and percussion, became wholly changed, and a fætid loose motion came away, but I know not the result of this case.

I ought to add, that although I have mentioned friction as having been employed, it was only done with a view of giving satisfaction to ignorant assistants, as it must necessarily be very inferior in efficacy to percussion, which, under the deception of friction, has always been enjoined. To those

also who may be induced to try this practice, it will be right to give this advice, viz. that well performed as it may be, it must be continued for more than a few hours to ensure a favourable result. In the above cases, five or seven hours are stated to have been the periods of time; but in some instances this is too short a time for the remedy to prove of effect. In three cases where total insensibility had taken place, the remedy had no effect whatever, although it was thought right to make a trial of it, even in these hopeless cases.

I remain, Gentlemen,
Your's, &c.

THOMAS SUTTON, M.D.

Greenwich,
Aug. 21st, 1833.

French Medicine.

Anatomical Anomalies.—No 1.—In an infant which lived fourteen days, and exhibited no signs of cyanosis, not only was the foramen ovale largely open, but the pulmonary artery, after having given off its branches to the lungs, curved round to the left side, and was continued down along the vertebral column in the place of the descending aorta, which was wanting. The aorta arose, as usual, from the left ventricle, and ascended towards the neck, where it bifurcated.

No. 2.—The veins on the anterior walls of the abdomen were found enormously enlarged and varicose, forming on each side of the linea alba two immense pyramidal tumours. There existed probably some obstruction in the vena cava, and nature thus endeavoured to compensate by enlarging the anastomosing veins between the iliac and femoral veins on the one hand, of the vena portæ and umbilical vein, (which was not obliterated), on the other. Lieutaud and Manec have reported similar cases of a magnified communication between the iliac and portal veins, and it is curious that this is the normal arrangement of the

vessels in many reptiles. — *Trans. Méd.*

German Medicine.

Extraordinary Cases of Fasting.—

Angelica Vlies was born in the neighbourhood of Delft, in South Holland, on the 20th of August, 1787. In her early years her constitution was very feeble and delicate, and she was much subject to cramps induced by intestinal worms, which she voided both upwards and downwards in large quantities. She enjoyed tolerable health till 1811, about which time she was first seized with violent hysterical paroxysms, during which the bowels were obstinately confined. Subsequently she had repeated attacks of chronic enteritis, and her appetite, which had been throughout very sparing, now began to fail altogether. At one time better, and at another time worse, she continued in the above state till May, 1818, when she discontinued the use of solid food entirely, and took nothing but drinks, chiefly whey. All medicines were rejected by vomiting as soon as swallowed. For upwards of four years she tasted nothing solid, with the exception occasionally of a little fish and salad, which she sucked, but never swallowed. In the spring of 1822 the attack of hysteria became so violent as to threaten death; an enema was given on the 10th of March, the bowels and also the bladder were then relieved, and this was the last time that any evacuation by stool or urine took place. About this time she refused nourishment altogether, fluid as well as solid; and at this time the catamenia, which had been regular but scanty, ceased. She frequently moistened her mouth with a little cold water, to abate the burning heat which she felt there. In July, 1822, an erysipelas appeared on the abdomen, which was relieved by the constant use of bread and milk poultices. In the following year she had a severe attack of dyspnoea, and fixed pain in the left side of the

chest, for which she was ordered a blister. In 1824, she had repeated attacks of sub-acute arteritis, which in 1825 were greatly diminished in frequency and severity. In October of this year she voided, after most excruciating suffering, a small quantity of urine and fæces; during 1826, she only made urine twice, and at each time only a few drops. Thus, from the 10th of March, 1822, to this period, she had relief only once by stool, and three times by urine. The Dutch medical commission were very anxious at this time to induce her to remove to the Hague, in order that an opportunity might be had of strictly inquiring into her case; she would not however consent to this, but permitted four nurses to wait upon her alternately for the space of a month, the expense of their attendance was defrayed by government. Soon afterwards a memoir was drawn up by Dr. Voorstman, and published at Delft, 1827. According to the authentic reports of the nurses, Angelica took no food, fluid or solid, from Nov. 11 to Dec. 9. During this time she used to moisten her mouth with tea, water, or whey, but she immediately spat the fluid out again, and the quantity was thus frequently somewhat increased, and certainly never diminished; she had no evacuation by stool or urine, but had occasionally belchings of wind. During the days she sewed, and amused herself with reading. She rose, or rather was lifted from bed, at nine, A. M., and was carried back at eleven, P. M., but she slept very little, being much distressed with headach, swoonings, and cramp. Her age at this time was forty-one, but her appearance indicated more than sixty years; her face was shrivelled, and her eyes dull and lustreless; her tongue was clean and dry, the skin was parched, the pulse normal in frequency, but exceedingly weak and small; the sensibility of the cutaneous, and also of the deeper nerves was so much impaired, that she was scarcely aware of her skin being pricked or pinched.

Every hour and a half she was seized with shivering, followed by a convulsive lateral agitation of the head; these fits generally lasted about two minutes.

Dr. Schmalz (who reports this and the following case in Hufeland's journal) visited her in Sept. 1828, and had an opportunity of being perfectly satisfied with the truth of the preceding statements; she told him she had not eaten or drunk any thing since the report of the medical commission, nearly two years before, and if we go back we shall find that this extraordinary abstinence had now lasted six years and a half, from March 1822. The patient told Dr. S. that she would very willingly take food if she could in any way swallow it, but that this effort was impracticable to her. Here the report ceases, and Angelica was still alive at the last date of the report.

SECOND CASE.—Anna Garbero, aged 40, had hitherto enjoyed moderately good health, although her appetite had been always remarkably sparing, her food consisted generally of vegetables once a day, and the bowels were not usually relieved above twice a week. Gradually the appetite became less and less, and once she passed forty days without touching any solid or fluid aliment. But it was not till Sept. 1825, that a total inappetence for food came on; it was after a very scanty meal, consisting of only a mouthful or two of cabbage, and a draught of wine and water, that she was seized at once with intense gastralgia which continued for some time, till copious vomiting was induced, from this date she was unable to swallow any thing, and even her spittle was thrown back when she tried to allow it to pass down. Up to the 7th of the succeeding January, she neither eat, drank, nor had any relief by urine, or by stool, the only appreciable evacuation was that of the catamenia, which though very sparing, returned regularly.

Dr. Schmalz visited her at this period. He found her so emaciated that she seemed a mere skeleton over

which a dry skin had been forcibly stretched.

The skin was scarcely sensible to pricking or the strongest pressure, the limbs were cold and corpse-like, the pulse small and scarcely perceptible, but yet regular in frequency. The patient was quite willing to make an effort whenever desired to swallow food, but it was of no avail, and at length the mere sight of any victuals, however simple, brought on the most painful vomitings. Thus matters continued till the end of June, at which time she became insensible and lethargic, the state of apathy continued till the 25th of the following November, when she quite suddenly and unexpectedly recovered her senses and her speech. Her strength became weaker and weaker, and finally was exhausted in death on the 19th May, 1828.

On a *post mortem* examination, it was discovered that the omentum majus was drawn strongly downwards, and had become adherent to the rim of the pelvis, thus leaving the small intestines quite uncovered. This change had been caused by the falling down of the transverse colon, which was lying in the pelvic cavity, it was distended with hard fæces, the small intestines were on the contrary contracted to mere cords. On carefully tracing the colon, it was found that the canal of the descending portion was so much obstructed by the swelling of its mucous lining, that the fæces could only with difficulty be forced along; the obstruction was still greater at the commencement of the rectum, and completely prevented the transit of any solid matters. The contents of the ascending colon were more fluid, of a dark green meconium-like colour, and most intolerably foetid, two lumbrici and several ascarides were found in the bowels.

The rationale of this latter case appears exceedingly simple. The patient was a beggar, and exposed to all the inclemencies of the weather, from which exposure no doubt chronic inflammation of the colon and rectum

had arisen; the appetite became directly impaired, the passage of the fæculent matter obstructed, and the general health became in consequence more and more disordered. Complete anorexia was the consequence of the accumulation of the fæces; the colon was dragged down by the weight, and at the same time the stomach and œsophagus were necessarily displaced in a similar direction, which must have seriously injured their functions. Besides, traces of a slow inflammation of the mucous coats of the small bowels and the stomach were found upon dissection. In short, the preceding case may be regarded as one of the melancholy results of neglected sub-acute enteritis, originally of the rectum and sigmoid flexure, and subsequently of the rest of the canal.—*Journ. der Pract. Heilk.*

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Operation for Femoral Hernia.—

At one o'clock on Saturday, August 24th, Mr. Stanley performed the operation for femoral hernia, in the operating theatre of this hospital, in the presence of a large number of pupils and visitors. The patient was a female, æt. 40. She had been subject to hernia for some time past, and the intestine having suddenly slipped down on removal of the truss and become strangulated, Mr. Stanley, after frequent futile attempts at reduction, found it necessary to operate. He was assisted by Mr. Earle, and having made the usual T incision through the integuments, he threw back the flaps, and cautiously dissected the various laminæ of fasciæ. The hernial sac being then discovered, he divided the stricture in the direction of Gimbernat's ligament; the hernial contents were then returned without any difficulty. During the operation scarcely three spoonfuls of blood were lost. The stricture in this case, as in most cases of femoral hernia, was formed by the superior part of the

iliac portion of the fascia lata. The patient after being about fifteen minutes on the table was carried to bed, and Mr. Stanley proceeded to make a few very general observations on the case, which, as they did not possess any particular interest, need not be inserted here.

Since the operation the patient has gone on well; several copious alvine evacuations have been procured; the pulse is not so feeble as it had been previous to the operation; there is, however, considerable anxiety of countenance and feverish irritability.

Disunited fracture of eighteen weeks' standing in a healthy man, æt. 45.—There is a very curious case of disunited fracture of the femur at present in the hospital. The fracture is of eighteen weeks' standing, and though the health of the patient is good, and he is a strong labourer about forty-five years of age, union of the fractured extremities has not as yet taken place. The fracture is almost as complete as it was on the day of his admission. In consequence of the failure of the splints in producing union, a tourniquet and strong bandages have been securely applied round the fractured part of the thigh with a view to attain that object.

Fracture of the Pelvis.—A stout athletic man, ætat. 35, was conveyed to the hospital on Thursday, Aug. 22nd, in a state of insensibility, having just fallen from a wall several feet in height. On examination it appeared that there was fracture of the front part of the pelvis, extending down to the acetabulum, which Mr. Stanley thinks is also fractured. The man is going on well, with strong bandages round the pelvis, but complains of great uneasiness in his position. Mr. S. desired the dresser to remedy this if possible, by placing a firm support under the pelvis.

ST. GEORGE'S HOSPITAL.

Diseases of the Patella—Necrosis of the Tibia—Amputations of the

leg, with Clinical Remarks.—On Thursday, August 22, Mr. Keate performed amputation above the knee in two cases. The one was for disease of the patella, the other for necrosis of the tibia. Both amputations were performed in the usual manner. After the operations, Mr. Keate remarked, with respect to the case of disease of the patella, "this patient had been in the hospital three years ago. At that time there was extensive ulceration of the cartilages of the knee-joint, and a consultation was held as to the propriety of amputating the limb. However, in consequence of the evident improvement caused by the application of caustics, we abandoned that determination; the patient was discharged, and seemed in a fair way of recovery. His occupation was that of a gardener. I did not see anything of him from that period till a few weeks ago, when he applied again to me for admission into the hospital. He had lost the use of his knee for a long time previously, and had suffered an immense deal of pain and agony. In short, the poor fellow seemed exceedingly anxious to have the limb removed, as it entirely prevented him from attending to his occupation, and rendered his existence miserable. Having taken him into the hospital, and tried every remedy without success, I have accordingly operated." Mr. Keate next proceeded to examine the limb. An immense quantity of scrofulous matter was found in the joint. The patella was soft, and had entirely lost its osseous structure; the entire joint was exceedingly diseased, and its morbid structure fully justified the steps Mr. Keate had taken in amputating the limb. "With regard to the other case," continued Mr. Keate, (necrosis of the tibia) "I do not know much of its history. The patient has been in the hospital since last April, and during that time I have frequently removed particles of dead bone from the tibia; the disease however lately presented a formidable appearance, and was making rapid

strides to the knee-joint. It is not unlikely that the knee-joint is already affected. The dimensions of the diseased limb you perceive have been unnaturally increased, while the other leg, and the rest of the man's body is in the last state of emaciation. About a fortnight ago, you may recollect, I took away a very large piece of the tibia in the ward." On dissection of this leg a large portion of fluid was discovered. There was considerable deposition of diseased osseous structure, the tibia was very soft and carious. On further examination it appeared that the disease had reached the knee joint. Both the cases have gone on well since the operations; the bowels have been kept open, and the patients have been put on broth diet. On Monday, Aug. 26th, Mr. Keate dressed the stumps. On removing the dressings the stumps presented healthy surfaces. On being informed that their bowels were inactive on Sunday, Mr. Keate ordered each

Oleum ricini, ʒi. statim.

Wednesday, Aug. 28. Both patients are going on favourably; they sleep well at night. Bowels in good order; pulse regular.

Femoral Hernia.—Elizabeth Chapman, whose case we gave in our last number (femoral hernia), has gone on favourably since the operation. Abundant alvine evacuations have been procured. Mr. Keate on dressing the wound last Friday found her very feverish, and she seems to labour under great nervous irritability. She seemed in great anxiety as to the success of the operation, and was crying the entire time Mr. Keate was dressing the wound, though she complained of no particular pain. Up to Wednesday, Aug. 28th, she has gone on most favourably.

OBITUARY.

DEATH OF MR. ALCOCK.

It is with feelings of considerable regret that we have to announce the death of Mr. Alcock of New Burlington-street. He was well known by many of his works, and justly

esteemed by every member of the profession who knew him.

LITERARY INTELLIGENCE.

A New English Version of Cuvier's great work "*Le Regne Animal*" is in process of publication.

Mr. Pettigrew has a work "*On Mummies*" in the press.

Dr. Ayre will shortly publish a work on the Treatment of Cholera, by small and repeated doses of Calomel.

Translations of the following works into German are announced—
Brodie on the Urethra.

Clement's Observations in Surgery and Pathology.

Lindley's Introduction to Botany.

BOOKS.

Baillie's Morbid Anatomy.

This work has reached its eighth edition, a sufficient proof of its value.

A Report on the Treatment of Malignant Cholera, by JOSEPH AYRE, M.D. 8vo. pp. 167. Longman and Co.

We shall notice this work in our Review department at an early occasion.

The Dublin Journal of Medical and Chemical Science, No. X.

CORRESPONDENTS.

THE SANCTUM.—It is our intention, on and after our first October Number, to devote a portion of this page of our Journal to "*The Sanctum*," in which all our correspondents may expect to be immortalised; those, therefore, who may wish for immortality on the 5th of October must express to us their wishes on the subject (post paid) as early as possible.

We have inserted Mr. Thompson's paper without, however, pledging ourselves to support his "*Plan*" to its full extent.

P. M.—If our correspondent has acted as an apothecary by compounding medicines and attending medical cases in 1807, he can do so.

H. H., Dorsetshire.—We shall bear in mind the suggestion of our correspondent.

Dr. Seeds must be aware that we cannot republish articles which have already appeared in our pages.

We are much obliged by the communication of our Edinburgh correspondent.

We shall notice Mr. Dyer's communication in our next.

A Constant Reader shall hear from us.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LIII., DELIVERED FEB. 15, 1833.

GENTLEMEN,—For the purpose of finishing the general view which I have lately been taking of the principal mechanical injuries of the body, I will now make a few observations on *contusions* and *sprains*.

Contusions.—A contusion, or bruise, is a mechanical injury of the soft parts, occasioned by the blow of an obtuse weapon, or by the violent collision of the soft parts against a hard body or surface, without any breach of the integuments; for if there were the latter mischief present, the injury would then rank as a *contused wound*. Besides the sudden and forcible compression of the soft parts, produced by a contusion—besides the inflammation which always follows the injury—there is a rupture of an infinite number of the minute blood-vessels of the part; and this circumstance explains why, after severe contusions, the swelling should come on so rapidly; and, in some examples, it comes on almost instantly, in consequence of the burst vessels being larger than usual, and the quick effusion into the cellular tissue. The same fact also explains why there should be that discoloration of the surface of a bruised part, which surgeons call *ecchymosis*—a dark blue, livid, and yellowish sort of discoloration of the skin, the most familiar example of which is seen in what is called a “black eye.” This arises from the effusion of blood into the cellular tissue from the small arteries and veins which have been burst by the violence of the blow. The various shades of such discoloration do not depend, however, merely on the effusion of blood, but on certain changes which it undergoes, the nature of which has not as yet been satisfactorily made out. No doubt the dis-

coloration is produced by the effusion of the blood itself; but the reason why, at different periods, this discoloration should be greenish, or yellowish, or livid, is not precisely known:—whether the effused blood may undergo any decomposition, or any change in consequence of the action of the absorbents, or from some other cause, I cannot presume to determine.

A contusion sometimes produces a rupture of more considerable vessels, and then the consequences may be dangerous, or fatal; thus, in a contusion of the head, there is sometimes an extravasation of blood within the cranium, in consequence of one of the arteries of the brain or dura mater being ruptured, or one of the sinuses being burst, the consequence of which will generally be death; for, though in such an instance as this, the quantity of blood lost would not endanger life by its mere abstraction from the system of the circulation, yet its pressure on an organ, so important to the whole economy as the brain, must produce very perilous and even fatal effects. In other examples, there will be an immense extravasation of blood in consequence of a severe contusion, without the accident being productive of any danger: thus, from a blow on the head, sometimes a branch of the occipital artery, or of the temporal artery, may be ruptured, and so much blood rapidly effused as to lift up the scalp to a considerable height from the cranium, as for instance, to that of two or three inches, and of course so as to occasion immense disfigurement. I have seen many such cases, which would have been truly alarming judging from their appearance alone; and, if the prognosis had been founded on this principle, that is, on the ground of the mere disfigurement, it would have been erroneous; for, almost all these external swellings, arising from effusion of blood after contusions, are removed by the absorbents with surprising power and expedition. You must not, therefore, judge of the danger of a contusion from the quantity of blood effused, but rather from the situation of the blood: thus, if there be an effusion of blood into the abdomen, produced by a contusion, then the situation of the extravasated blood, independently of its quantity, will be a source of considerable danger. I had a

VOL. IV.

M

patient, about fifteen months ago, who, in a fall, struck the sacrum violently against a stone step; the result was a prodigious swelling as large as the man's head, and equal in size, I am sure, to that immense protuberance on the sacrum of the Hottentot Venus, who used to be exhibited in London some years ago as a curiosity; but this swelling, immense as it was, disappeared completely under common treatment. It was not necessary to make any opening in it; and, in the course of seven or eight weeks, it had entirely subsided.

I should say, gentlemen, that it is generally better in these cases to leave the blood to the action of the absorbents, than to make an opening for its escape, for a reason which I will presently explain to you; in fact if, in the particular case I have just alluded to, I had made an opening in the swelling—and, by the by, one of the surgeons who saw it with me considered it impossible to avoid doing so,—if, I say, I had made an opening, I should not have got out all the blood, and the consequence would have been, that what remained would have putrified; for directly the atmospheric air has access to extravasated blood in the temperature to which such blood is usually exposed, putrefaction of the effused mass takes place rapidly, the surrounding parts inflame, suppuration and large abscesses follow, and frequently sloughing.

I may next remark, gentlemen, that the severity of a contusion does not depend simply on the violence with which it has been inflicted; and a moderate contusion of the head may cause urgent and considerable danger by extravasation of blood within the cavity of the cranium, and consequent pressure on the brain. A moderate blow on the hypogastric region may also rupture the bladder, if that receptacle happen to be full of urine at the moment. This fact is illustrated in two preparations on the table: one of them was taken from a patient who had been drinking, and who on going suddenly out of a light room into the street at night, struck the lower part of his abdomen against a post; and the bladder happening to be full at the time, was burst by the blow. The consequences were fatal, from the extravasation of urine resulting from the rupture of the bladder. The other preparation was taken from a patient of my own; a fine young man, who, as he was wrestling one day in the King's Bench, fell under his antagonist, whose knee came forcibly upon the hypogastric region, and ruptured the bladder, which happened to be very full at the moment. The same remarks apply to the intestines, which, if they are full at the time of a contusion being received on the abdomen, are in considerable danger of being burst, and their contents are likely to be extravasated. These circumstances will make you understand, that the danger of some contusions depends on the empty or distended state of the parts at the time when the violence is applied. Sometimes the danger

of a contusion depends on its effect on a distant part from that immediately injured, which effect is called a *contrecoup*. A remarkable example of this sort of injury is mentioned in the writings of Mr. Pott: a person fell with great violence on the tuberosity of the ischium, and no other part of his body was struck, yet he had every symptom of a violent concussion of the brain.

Now, gentlemen, there are three indications to be attended to in the treatment of contusions; the first is, to prevent or keep down inflammation; because, when a part has received a severe blow, there is of necessity a disposition excited in it to inflammatory action. You always remark more or less swelling in cases of contusion, for the effusion of blood from the ruptured vessels is immediate; and then inflammation will follow, unless some means be taken to prevent it. Sometimes the inflammation will be so violent as to lead to the formation of abscesses; and this will especially be liable to occur, if the patient be allowed to move the injured part, and no means be adopted for subduing the inflammatory action. The best applications for the fulfilment of this first indication, are in the beginning cold ones; cold evaporating lotions are the most proper at first; the application of cold tending to check the inflammation, and to restrain a further effusion of blood from the ruptured vessels. You must therefore at once see the reasons why cold applications should be so beneficial. But, in severe cases, it will not be sufficient to employ merely local treatment; antiphlogistic measures ought to be pursued further. In particular bleeding should be employed, purgative medicines administered, a low diet directed, and other general antiphlogistic plans put in execution; but, above all things, it is necessary to keep the part perfectly quiet. There are some exceptions to the use of cold applications; certain patients do not bear them well, and express a strong objection to them, especially when it is proposed to apply them to certain parts of the body; for instance, you would not judge it right to apply them to a female at the time of her menses, or to any person who is particularly disposed to inflammatory affections of the chest or lungs; under such circumstances you would avoid the use of cold applications. I may add, that in all cases after a certain time, you will find, that the application of cold does not afford that relief which it may have done in the commencement; it is considered generally beneficial, therefore, after a time to exchange them for warm ones, such as fomentations and poultices.

The second indication is to promote the absorption of the extravasated blood, the removal of the *ecchymosis*. You cannot safely attempt to do this, however, until the inflammation immediately following the accident has subsided. At all events, all active inflammation should be removed before the

most efficient remedies, called for by the second indication, can be prudently tried. The dispersion of the ecchymosis is promoted by the use of what are called *discutient lotions*, which generally contain the *muriate or acetate of ammonia*, *spirit of wine*, or *diluted acetic acid*. You may also apply to the part, the *liquor plumbi acetatis dilutus*, and perhaps, while a degree of acute inflammation still continues, this is the best application as a mild discutient to begin with, and after a time, when the inflammation has been still further subdued, you may have recourse to stronger discutient lotions, or even liniments, containing camphor or ammonia. Sometimes, also, pressure is exceedingly useful in dispersing the effused blood. In many cases, iodine has been employed in liniments for the purpose of exciting the absorbents to take up the extravasated blood; but it should not be used till the inflammation has been sufficiently removed.

The third indication in the treatment of contusions, is to restore the tone of the parts, that is, to bring them into a state in which any weakness or loss of action in them will be obviated, and they will regain a capability of performing their several functions. After a severe contusion, you will find that the parts always remain for a certain time exceedingly weak, and if they are at this time excited too freely, they will become the seat of an oedematous swelling. Now, the indication at present under consideration, is fulfilled by applying camphorated liniments, or having recourse to friction, shampooing, or the pumping of cold water on the parts; but perhaps no means is more effectual for restoring the tone of the parts, than pressure by means of bandages, or a laced stocking, an India rubber roller, or, if it be the ankle which is affected, strips of adhesive plaister, applied in the manner which I have formerly pointed out to you, namely, in circles, alternately in the perpendicular and transverse directions. When much rigidity continues, as well as weakness of the part, you may try *passive motion*, the meaning of which term I have already explained to you on more than one occasion.

There are certain instances, in which you will be obliged to deviate from the advice I have given you, not to make an opening in contused parts for the purpose of letting out the effused blood; for sometimes matter will form in the swelling, and the absorbents will fail in taking up the extravasated fluids. Then you must make an opening, not only to discharge the matter, but also to let out as much blood as possible. Under such circumstances, the opening ought to be a free one. Afterwards the case is to be treated as a common abscess.

With respect to *sprains*, gentlemen, when a joint is forcibly moved in a direction in which it was never intended to move by nature, or when it is moved in a natural direction beyond a certain limit, then the

ligaments and tendons become stretched, and the surrounding parts suffer considerable injury. There is not merely a stretching of the ligaments, but considerable injury done to the integuments and other soft parts. I may say, then, that when a joint has been moved in any direction further than the natural conformation of the bones, and the disposition of the ligaments will properly allow; or if it has been twisted, yet not so as to produce a dislocation, then the injury ranks as a *sprain*: or I may say, that a violent twist of a joint, or a forcible movement of it in a direction or degree for which nature has not fitted it, but without dislocation, is technically called a *sprain*. There can be no doubt, that in a sprain, the ligaments are not only violently stretched, but often partially torn; neither can it be doubted, that after a severe sprain, the muscles of the limb are considerably injured through the medium of their tendons, which the accident has caused to be violently drawn in one particular direction. The sheaths of the tendons themselves, we know very well, are likewise subject to inflammation.

The ginglymoid joints are observed to be those which most frequently suffer from the effects of sprains, and when you reflect a moment, you will see the reason of this fact. The orbicular joints are adapted for motion in every direction, and this circumstance must, in a great measure, protect them from sprains. The shoulder joint is one that admits of motion in every direction, and, therefore, is not frequently sprained; if the motion be carried beyond a certain point, there will generally be a dislocation. But, ginglymoid joints being restricted to motion in two directions only, if they are forced to move in any other direction, then they become sprained. It is then the capability of orbicular joints to move in every direction, which protects them very much from the effects of sprains; yet you must not adopt the opinion of some surgeons who contend, that orbicular joints are entirely free from all liability to sprains. Any person, who has had his arm forcibly and suddenly carried a considerable way behind his back, knows by experience that the shoulder joint may be sprained; and when the lower extremity is suddenly placed in a state of abduction beyond a certain point, if it be not carried so far as to produce a dislocation, it will suffer the kind of injury which is called sprain.

Gentlemen, the symptoms of a sprain are, first a considerable degree of pain in the injured part, a severe and peculiar kind of pain, which is supposed to arise from the injury done to the ligaments; it is in fact often suspected, that the sickness and faintness, following a sprain, are more owing to the mechanical injury done to the ligaments, than to the mischief done to other soft parts. Then, gentlemen, a rapidly formed ecchymosis is another usual consequence of this kind of accident.

In elderly persons, sprains are often very

tedious cases, occasioning as much confinement as a broken leg, and, in many instances, several weeks transpire before all the inconveniences of the accident disappear. It is a curious fact, that sprains are not uncommonly longer in getting well, than the pain and weakness left after the dislocation of such a joint as the shoulder. The inconveniences of dislocation of the shoulder are usually not felt beyond ten days or a fortnight after the reduction, and the individual then becomes able to move the limb about strongly and freely; but the effect of a simple sprain of the ankle or wrist are generally much longer in going off.

One essential part of the treatment of sprains consists in keeping the joint perfectly quiet; this is a principal indication. The next is to take measures calculated to prevent the super-vention of a serious degree of inflammation, and with this view, topical bleeding is often called for. For the purpose of relieving a severe sprain, you may apply leeches to the joint, or employ cupping; the latter plan is often had recourse to, when the sprain is attended with great violence, excessive pain, and much inflammation and swelling. Cold applications are also as useful in sprains, as in common contusions, but, after a few days, greater benefit will be derived from the application of emollient poultices and fomentations. Indeed, the treatment of these cases is conducted precisely on the same principles as that of contusions; for, in sprains, where the inflammation has subsided, liniments, and discutient lotions become as useful and proper, as they are under similar circumstances in contusions. In particular you must be careful to keep the joint perfectly quiet; for, such is the effect of prematurely moving the part after a sprain, that, even after all the acute inflammation is over, you will find the disturbance renew the pain, and bring on a troublesome degree of inflammation again. When the parts about the joint become cedematous, pressure is one of the best means you can employ. Pumping cold water on the joint deserves also praise. Straps of adhesive plaister, applied in the way I have already directed, are very useful for keeping up pressure, supporting the parts, and limiting the motions of the joint. You may form a sort of case for the joint with straps of adhesive plaister applied circularly and perpendicularly in an alternate manner. The plan has likewise a most useful effect in removing the kind of oedema left after a severe sprain.

A sprain is sometimes a more serious accident, in consequence of its occurring in a scrofulous subject; it will then frequently become the exciting cause of one of the worst diseases of joints, namely *white swelling*. When you think that the tediousness of recovery from a sprain is owing to a scrofulous diathesis in the patient, you must blister the part as soon as the acute inflammation has subsided. I make it an invariable rule, when I have a case of severe sprain in a scrofulous person,

and find that it does not readily get well, to blister the part, as soon I have removed the active form of inflammation.

Now, gentlemen, I will, if you please, employ the short time remaining, in asking you a few questions on subjects which we have lately been considering.

CLINICAL LECTURES

BY DR. MAC ADAM,

Delivered at the South Eastern General Dispensary, Dublin, Session 1832-33.

LECTURE VI.

Pathology and Treatment of Dropsy.

GENTLEMEN,—We have lately had several cases of dropsy among our dispensary patients, a few of which I have selected as subjects for our consideration this evening; but previous to a recital of cases, I think it may be instructive to the junior students to make a few general observations on this disease. I do not propose, however, to go into any detail of the species of dropsy at present, but shall principally direct your attention to that form of the disease of which the cases we have recently met with afford illustrations; as all the varieties of dropsy are very common among the poor of our district, abundant opportunities will be afforded you at a future period of witnessing the other forms of this disease.

Dropsy, you are aware, is the general term applied to a collection of serous fluid in the cellular tissue or natural cavities of the body. The word merely expresses an effect, without implying any theory as to the cause of the disease; in fact, the effusion of serous fluid is but an invariable symptom; it is the result of previous morbid actions, which may be different and even opposite in their nature in different cases. Before, therefore, proceeding to a rational method of cure, we should first investigate what deviation from healthful action or structure has caused the serous effusion, and having made this discovery, we shall be enabled to attack the root of the evil, which when eradicated, the effect in general will soon disappear, or be easily removed by appropriate means.

Whether dropsy proceeds from increased exhalation or diminished absorption, is yet undecided, the only points that we can assert as proved in the theory of this disease, are, as Dr. Darwall observes, "1st, that the balance between exhalation and absorption is broken, in consequence of which more fluid is poured out than is taken away; and 2nd, that this may take place from over activity or from debility of the general system."—*Cyclopædia of Medicine*; article DROPSY.

Dropsies may be either acute or chronic, idiopathic or symptomatic, general or local, sthenic or asthenic. A large proportion of dropsies are symptomatic of a disease of some internal organ, which may be either an inflam-

mation or an organic affection. Of the first kind we have an example when dropsy supervenes as a consequence of peripneumonia; of this I lately met with a case among our dispensary patients, in a boy seven years old who was swelled from head to foot with anasarca, there was some dyspnoea, but no pain in the chest, nor was the cough very urgent. The stethoscope, however, revealed both to Mr. Smyly's ear and mine, the sounds characteristic of intense inflammation of the substance of the lungs. The boy recovered rapidly after venesection, antimonial solution, and the other usual treatment for peripneumonia, and the serous effusion was afterwards quickly removed by the use of diuretics and purgatives. Dropsy is often the effect of organic disease of the heart; the peculiar symptoms of which frequently precede the appearance of the serous effusion for a considerable period. This species of the disease is often very easily relieved or cured for a time. I recollect a patient whom Mr. Smyly and I attended occasionally, for two or three years before his death. He had well marked symptoms of disease of the heart, as was afterwards ascertained to have existed on a necroscopic examination; this man had at several times serous effusion in the lower extremities and abdomen, which was removed with ease, by the use of small bleedings, and purgatives; at one time the lower limbs were swelled to such an enormous degree, that I considered the case as nearly hopeless, yet very much to my surprise, it entirely disappeared in the course of a few weeks under the employment of the treatment above mentioned. Inflammation of the peritoneum, disease of the liver, spleen, pancreas, kidneys, uterus, or ovaria, may produce dropsy, or it may arise from the repression of eruptions, the suppression of the catamenia, or any customary evacuation. It also often succeeds scarlet fever, and sometimes measles or erysipelas, it has in some instances originated from a powerful impression on the mind. Dr. Bateman mentions a case in which it came on in the course of a night after excessive fright, and was cured by the exhibition of cinchona. Dropsy also occasionally follows parturition, arising in some cases from debility unaccompanied by any sign of increased action, but in many instances where it occurs in the puerperal state, it is the consequence of peritoneal inflammation. Dropsy of the asthenic kind, may also be caused by hæmorrhage, any excessive discharge, or any cause which induces debility in a constitution predisposed to the disease.

We thus observe that the disease may arise from various and sometimes opposite causes, in some cases from local disease, when it appears to be produced by an obstacle to the free circulation of the blood, in other cases from mere debility, independent of disease of any particular organ, occasionally from an affection of the nervous system, as in Dr. Bateman's case, and lastly being the consequence of inflammatory action of the vessels of

the cellular tissue of all or the greater part of the body, as occurs when it is the effect of exposure to cold, wet, or the other causes which excite inflammation generally. This latter form of dropsy, will more especially engage our attention this evening. It generally comes on in a short time after the application of the exciting cause, is preceded by rigors, is attended with a full, frequent, and sometimes strong pulse; heat, thirst, headach, and other pyretic symptoms will generally precede or accompany the commencement of the serous effusion, an affection which forms rapidly, is often in considerably quantity, and frequently extends over a large portion of the cellular texture of the body. It has been called inflammatory dropsy, and may either co-exist with, or be totally independent of, an inflammation of an internal organ. In the latter case the disease may be considered as purely idiopathic, but I can best illustrate this form by describing a few cases which have lately occurred among our patients. I shall begin with

P. B., ætat. 33, of a leucophlegmatic temperament, a job car driver by trade, of rather intemperate habits, whom I found on my first visit affected with some degree of tumefaction of the abdomen, and considerable œdema of the legs and feet. The face also was a little swollen. He complained of some tenderness on pressure in the right hypochondrium, immediately below the lower margin of the ribs, and of occasional pain in the right shoulder. Tongue little whitish; pulse 66, full and strong; bowels rather purged; some dyspnoea, slight perspiration occasionally, urine undiminished in quantity. Was taken ill about three weeks before my first visit, after having been exposed to cold and wet, with rigors, shortly after which he perceived a swelling in his abdomen and lower extremities. A few days afterwards he had an attack of vomiting and purging of green and yellowish matter, which continued to recur occasionally, for two or three days, and then ceased, it was unaccompanied by any cramps or coldness of the limbs; during its continuance the lower extremities became more swollen, and the œdema got very considerable after the cholera had disappeared. Previous to this attack, he had been for some time subject to pain in the right hypochondrium and in the tip of the left shoulder, occasional headach, and bitter taste in the mouth. *Fiat venesection ad 3xvi.*

On the next day he felt better, and experienced much relief from the bleeding; all dyspnoea gone; slept well last night; bowels natural; urine copious.

- R. Pil. hydrarg. ʒij; Pil. scillæ comp. ʒij;
Pulv. digital. gr. xij; M. fiat massa in
pil. xij. æque dividend., sumat j. ter die.
- R. Spirit. æther nit. ʒiv; Potass. nit., potass
carb., ʒiiss; Syrup. scillæ ʒss; Mist.
camphor, ʒviij. M. fiat mistura, capiat
cochl. ij. ampla ter die.

This mixture and the pills were continued

a few days, with some unimportant alterations, with the effect of a rapid decline of the swelling both of the abdomen and extremities, and a mitigation of all the symptoms. He was also occasionally purged with supertartrate of potass. In about eight or ten days pyralism was fully established; the gums and inner surface of the cheeks became sore; he was considerably better; swelling of the abdomen quite gone, and the œdema of the lower extremities much diminished, but most perceptible towards evening. Had some pain in the right hypochondrium last night. Pulse 72, full; urine abundant.—Vesicat. hypochond. dext. Omit. pil. et mistura.

R. Pot. carb., pot. acet., āā 3ij; Spirit. æther, nit., acet. scillæ, āā 3ss; Tinct. digital., m xxx; Mist. camphor, 3vi. M. capiat cochl. ij. ampla ter die.

He continued to improve under the use of this mixture; and a few days afterwards, when I called to see him, I found him out, having resumed his usual occupation. His wife reported that the swelling had entirely disappeared, and that he was quite free from all complaint.

This case exhibits a very fair specimen of inflammatory dropsy in a mild form, and also illustrates some points in the pathology and treatment of the disease generally. I shall, therefore, take a review of the predisposing and exciting causes to which this patient was exposed, the symptoms which he presented, of the prognosis and diagnosis which appeared to me deducible from a consideration of all these circumstances, and afterwards give my reasons for the line of practice which I adopted.

The predisposing causes in this case were, 1st. The temperament of the individual; 2nd. His habits of life; 3rd. His previous state of health. He was of the phlegmatic temperament. You are all aware that physiologists have long been in the habit of classifying constitutions according to certain physical and moral differences, depending on the various proportions and relations among the parts, which make up their organisation, as well as upon the different degrees in the relative energy of certain organs. These distinctions, I conceive, are founded on nature, but the detail belongs more properly to the physiologist; however, as far as it bears on the subject we are considering, I shall allude to it. The phlegmatic temperament is characterised by Dr. Gregory as exhibiting a "lax and feeble structure of body, in many cases attended with obesity, pale countenance, skin smooth without hairs, hairs white, pulse slow and feeble, blood-vessels small, fluids unusually watery, and languid in their motion, &c. &c." Our patient presented this general appearance. Such constitutions, is it obvious from the predominance of serous particles in their system, and also from the low degree of vital energy which they possess, will be more liable to dropsical effusions when exposed to the exciting causes,

than individuals of more active circulation and less diluted fluids. The habits of life of our patient also concurred with his temperament in rendering him liable to dropsy: he was intemperate—probably a dram-drinker. This vicious practice would operate in two ways in predisposing him to this disease; first, by inducing a general debility of the system, and secondly, by causing a diseased state of the liver, which we know is frequently productive of dropsical effusion;—this latter state, from certain symptoms to be afterwards considered, we had some grounds to suspect existed in this case. Our patient, then, being predisposed by temperament, habits, and previous disorders, to dropsy, was exposed to a powerful exciting cause, namely, cold and wet (probably from his occupation in life) long continued, while his body was in a comparatively inactive state. The immediate effects of this exposure were rigors, and some swelling in the abdomen and feet, with some symptoms of cholera, which, however, soon disappeared, and which probably originated partly from the epidemic influence not yet quite extinct in this city, and also perhaps from a deranged state of the liver. This swelling continued to increase, and there could be no doubt of the diagnosis as far as the existence of dropsical effusion was concerned. The œdema of the feet, legs, and face, presenting a whitish uncircumscribed tumefaction, pitting on pressure, and the co-existence of the abdominal swelling, all sufficiently indicated the presence of dropsy; but the point of diagnosis to be determined was, what species of the disease existed—whether it was dropsy dependent on disease of the liver, or connected with an affection of some other viscus, or arising from general debility, or caused by inflammatory action. The latter opinion appeared to me most correct, for these reasons, namely, the exciting cause being most likely to produce such an action on the system; the swelling being preceded by rigors, which very frequently usher in inflammatory action; the rapidity with which the swelling set in and increased; and the character of the pulse, which was full and strong. There appeared, however, some reason to suspect disease of the liver; the patient was a dram-drinker. He also exhibited some symptoms of hepatic disease, such as tenderness on pressure in the region of the liver, and pain in the right shoulder. He had been subject to pain in the right hypochondrium, and in the tip of the left shoulder, headach, and bitter taste in the mouth, for some time previous to his present attack. Might not, then, the dropsical effusion be the consequence of an affection of this organ? I think it likely that some degree of hepatic inflammation might have been present in this case along with the dropsical effusion, and probably have contributed to aggravate it; but I feel convinced that the main exciting cause of the disease was a general inflammatory action producing serous effusion. The dropsy arising from disease of the liver

is generally chronic in its character, unattended with rigors, full pulse, &c. Symptoms of hepatic disease and derangement of the stomach usually precede it for a considerable time. It also frequently assumes the form of pure ascites, and is not uncommonly attended with an icteroid colour of the skin. It is obvious these circumstances did not exist with our patient, neither were there any symptoms indicating an affection of any other internal organ; and the age, previous state of health, and the rapidity with which the disease progressed, excluded altogether the idea of the effusion being caused by general debility. Our diagnosis, then, appeared fairly deducible from a close consideration of the symptoms and history of the case.

Having determined on the nature of the disease, the next point of inquiry was, what prognosis was most probable. It appeared to me that the prognosis, on the whole, was favourable. The patient was a young man; his constitution not as yet much impaired by his irregular habits; the affection was that species of dropsy which in general may be subdued by depletion; it was not very aggravated in degree; and the remedies first used were speedily followed by a mitigation of all the symptoms; we had therefore every encouragement to proceed on an active and decided plan of treatment, and the result realised our hopes. Inflammatory dropsy being then presumed to exist, our first object was to reduce the increased action which had given rise to, and probably was still increasing, the effusion. Venesection was accordingly performed to the extent of sixteen ounces, with the effect of a mitigation of all the symptoms; and another advantage was also gained—that of rendering the system more susceptible of the influence of medicine than it would be while the inflammatory action continued unabated. The next remedy was intended to keep up the effect produced by the bleeding, to excite the absorbents to take up the effused fluid, and to stimulate the kidneys to increased secretion. A combination of digitalis, mercury, and squill was therefore used. The digitalis being calculated to lower arterial action, while at the same time it excites absorption; the mercury produces the latter effect, while it also promotes secretion; and the action of the squills is more exclusively directed to the kidneys. Diuresis was rendered more certain and rapid by exhibiting, in the intervals between the pills, a fluid mixture, consisting of several diuretics combined, for this class of medicines act with much greater power when several are combined together, than when the formula consists of but few ingredients; and it has even been asserted, with some truth, I believe, that the effect is often in proportion to the complexity of the prescription.

Supertartrate of potass was also used occasionally as a purge, which was not only well adapted to produce watery dejections, but also answered another important end, that of

acting with the mercury in its effect on the liver, which, as I before mentioned, probably also partook of the inflammatory state existing in the whole system. It has been observed of this salt, that it often succeeds in evacuating bile when other means fail, and this remark I have seen verified in practice, having often observed green stools follow the exhibition of this medicine. A blister was also applied to the hepatic region. The objects then we endeavoured to accomplish were, first, the reduction of inflammatory action; secondly, exciting the absorbent system; thirdly, stimulating the kidneys to increased secretion; and, fourthly, the removal of an inflammatory or congested state of the liver, and the result of the case seemed to confirm the propriety of our plan of treatment.

I have thus entered somewhat minutely into a consideration of the nature and treatment of this case, because I conceive the closest investigation is of the greatest advantage to the medical student, I would earnestly advise you not only to observe accurately, and to treasure up in your recollection, the phenomena which the case to which you are directing your attention exhibits, but also to exercise your understanding in reasoning on the symptoms, to endeavour to form a decided diagnosis and prognosis from your own judgment, to lay down the plan of treatment which would appear to you most likely to be successful, to consider the individual properties of the medicines you may select, the most judicious mode of combining and exhibiting them, to compare your conclusions with those of the more experienced practitioner, and also with the result of the case. You will, it is true, by this independent mode of thinking, often at first be mistaken in your judgment, but the discovery of your errors will be in itself a source of instruction. You will not only be less liable to err in similar cases in future, but you will learn caution in forming your conclusions, your habits of observation will be sharpened and improved, and you will be preserved from adopting an empirical routine of practice.

The case which we have been considering afforded an example of inflammatory dropsy affecting the lower extremities, the face, the abdomen, and probably the thorax in a moderate degree, and only requiring one bleeding, of no great extent, the use of diuretics for a short time, and purgatives to effect its removal. But cases do occasionally occur of much greater severity, requiring venesection to be carried to a degree which would appear quite unjustifiable to a practitioner who had not an opportunity of witnessing the result of the practice. I recollect having seen a most striking instance of this kind, a good many years ago, in the clinical ward of the Edinburgh Royal Infirmary; a detail of the case has been published by Dr. Graham, in the Edinburgh Medical and Surgical Journal, April, 1832, but it illustrates so strongly the

utility of active depletion in this species of dropsy, that I think I cannot occupy your time better than by giving you a short account of it. The patient, a strong Irish labourer, *ætat.* 21, was, on his admission, swelled all over the body with anasarca. There was some fluctuation in the abdomen; bowels open; urine scanty; pulse full and firm; considerable thirst. Three days previous to his admission he had been obliged to leave work in consequence of severe rigors; uneasiness in the stomach; urgent thirst, and vomiting of a bitter fluid, which soon ceased when the oedema began. Hydragogue cathartics and diuretics were tried for two days without effect; the swelling continued to increase, and the other symptoms became aggravated; 3xx of blood were then abstracted, with no effect on the pulse, but with some relief. The next day the same quantity was taken with little alleviation. Two days afterwards, 3xxxij more caused the pulse to rise in frequency and become softer. For several days after, the lancet was laid aside, the oedema went on increasing, attended with dyspnœa; he had a severe asthmatic fit; the pulse 68, large and firm. At this time he was distended like a sack, his weight and bulk preventing motion; his eyes sunk and small; his appetite gone, his nights restless; 3lxxij of blood were abstracted in one bleeding, the first 3xviiij flowed moderately free, the remainder in a very full stream; the pulse continued rising in firmness, and only becoming softer at the very last. There was no tendency to syncope; about half an hour after the bleeding he could lie in any position, and said he did not feel enfeebled, but became faint on assuming the erect posture. There was a slight buffy coat on all the blood; he said that he felt quite happy after the bleeding, and requested that it might be repeated; he slept well the following night, and every night afterwards. On the evening of the next day, in consequence of some return of oppression and increased fullness of pulse, he was bled again to 3xxxij, the blood was buffed and cupped, and from this period the disease rapidly declined. His bowels were purged by medicine, and the kidneys acted freely without the exhibition of diuretics.

This patient lost on the whole *one hundred and seventy-six ounces of blood* in the course of nine days, the two last bleedings amounting to *one hundred and four ounces* were taken in the course of thirty hours. The two first bleedings seemed to do no good, a little was effected by the third, which was carried to the extent of 3xxxij, the fourth, amounting to 3lxxij, seemed to produce a decided effect on the disease, which was confirmed by the fifth and last of 3xxxij. I have given you but a short outline of the history of this case, the details of which you will find in the journal before mentioned, together with some valuable clinical remarks; it was one which attracted considerable attention at the time, and is the

most remarkable example I believe on record of the extent to which blood-letting may be carried with success in the treatment of this form of dropsy, the good effects of which are not limited to the reduction of the inflammatory action which has caused and continued to augment the serous effusion, but it also assisted in promoting absorption, and in restoring the secretions of the kidneys and bowels, rendering them besides more susceptible to the action of diuretics and purgatives. Another most important object is also often accomplished by venesection. Inflammation of an internal organ not unfrequently co-exists with, and probably may prove the cause of, the dropsical effusion; in such cases the venesection will be obviously the most efficient means we can employ; but I would not of course recommend such immense depletion in ordinary cases; it is rarely, indeed, that such extreme measures are necessary. In the case I have just alluded to, the patient was a young man, of a full and vigorous habit of body; the inflammatory symptoms were strongly marked, and the effects of the flow of blood carefully observed by Dr. Graham, a physician of great sagacity and skill, and the result proved the propriety of his practice in this individual's case; but if this treatment was indiscriminately adopted in non-inflammatory cases, or with patients of less powerful constitutions, the result would most likely be injurious or fatal. The case illustrates a very important principle in practice, namely, that the same disease affecting different individuals may require very different degrees of the same treatment. In some patients, a few ounces of blood abstracted produce all the effects of a full bleeding; others similarly affected, may require the venesection to be carried to thirty or forty ounces to produce the same impression on the system. I recollect having been some time ago called late at night to see a poor woman residing in this neighbourhood, whom I found labouring under all the symptoms of acute enteritis; she was of a very delicate constitution, and I feared much that venesection could not be carried to the necessary extent: I stood by until the blood flowed, and was much surprised to find that after she had lost five or six ounces, there was a most decided effect produced, both on the system and on the local symptoms, and she recovered rapidly without requiring a repetition of the bleeding. In this instance the loss of a few ounces of blood produced as much effect on the disease as I have known thirty or forty produce in other cases.

The cases we have been just considering were instances of general inflammatory dropsy, but this affection may be limited to a particular part of the body; in fact, be a strictly local disease, though derived from a morbid impression on the system. I have had lately a striking example of this in the case of a patient named E. D., *æt.* 24, of a phlegmatic

temperament. When I first saw her she exhibited the following symptoms:—

The face was very much swollen, and presented a whitish oedematous appearance; the swelling circumscribed, but principally occupying the left cheek, and extending around the left eye; pulse 96, full and strong; tongue white; no cough or dyspnoea; no tumefaction of abdomen, or any oedema of upper or lower extremities; some headach, a vesicular eruption on the upper lip; bowels confined; urine copious; four days ago her feet were wetted, the next day had rigors and pains in her limbs, and the following night the swelling of the face appeared. I directed her to be bled, and to take an electuary of jalap and supertartate of potass. She was bled to 3x. On the next day I found the swelling of the face nearly gone, the blood was not buffed, but slightly cupped, with abundant separation of serum; bowels not opened by electuary; a gum-boil had formed. She took a dose of sulphate of magnesia, which operated freely. In the course of a few days the swelling entirely disappeared, and she made no complaint but of debility. I directed her to use a mixture composed of ferrum tartariz., pot. supertart., and tinct. gent. comp. and she has continued to improve in her general health ever since. My reason for mentioning this slight case is not only to present to your attention the lighter and severer forms of disease, in order that you may have an opportunity of forming correct ideas of the different grades of the same affection, but I wish also to show, that serous effusion may be caused by inflammatory action of the vessels of a certain part of the body. If this case had been left to run on its natural course, the effusion would have probably extended itself more or less; but we see that a very moderate bleeding, in this case, produced as decided an effect on the disease as the large abstractions of blood did in the case that I have lately alluded to.

I shall now make some observations on the treatment of inflammatory dropsy, as supplementary to the few remarks I ventured upon when giving my reasons for the practice I adopted in the first case I recited. I then alluded to the effects of venesection, diuretics, and purgatives, in subduing inflammatory action, promoting absorption and diuresis. But bloodletting and evacuants have often produced these effects; in an opposite state of the system, debility may supervene, and continue or renew the effusion. Under these circumstances our object should be to restore strength to the constitution, while we stimulate the absorbents to action. The first indication is to be accomplished by the exhibition of tonics, such as preparations of iron, sulphate of quinine, or other vegetable bitters. The tonic I have been most in the habit of using in such cases is the ferrum tartarizatum; it may be given in doses of from gr. x. to 3ss. in powder or bolus, or in solution combined with an

aromatic or bitter. The form that I have in general used is the following:—

R. Ferr. tartar. ʒ. iv.; spirit. junip. comp. ʒss; mist. camphor., ʒviiss. M. capiat ʒi ter quaterve die.

During the exhibition of this combination I have seen the dropsical swellings which had been reduced by other means continue to decline, and finally disappear, while the appetite and general health improved rapidly.

Iodine is another medicine of great power in these forms of dropsy, where no active vascular action exists. In some cases it surpassed my expectations in its effects, both on the general health and also on the serous effusion. The form that I have used is that recommended by Lugol, and is composed of Iodinæ gr. ʒ; potass. hydriod. gr. ʒss; aq. distill. ʒviij. M. Of this solution I begin by giving a table-spoonful three times a day. It improves the appetite and strength of the patient, acts as a diuretic, and also stimulates the absorbents. I recollect a case of ascites probably consequent to peritonitis, which I attended some time ago. The patient was an emaciated young woman, exhibiting every sign of debility from long indisposition. Her abdomen was swollen as large as that of a woman in the ninth month of pregnancy; there was no considerable oedema of the lower extremities. When I first saw her I considered her case as nearly hopeless, but I resolved, from theoretical views, to give iodine a fair trial. I accordingly ordered the solution of Lugol, and also directed the abdomen to be rubbed all over several times a day with a mixture of the mercurial and ioduretted ointment. In a few days there was a rapid decline of the abdominal tumefaction, with increase in the quantity of the urine, which continued; the patient's general health improved, and in the course of a few weeks her abdomen was not larger than that of a young unmarried female. She was slightly salivated while rubbing the ointment; in a short time she was able to attend at the dispensary nearly recovered. I then ordered her the solution of tartarised iron, with the best effects; and when I saw her last she was so improved in her general appearance that I should not have known her, if I had not been in the habit of seeing her almost daily. I never was so agreeably surprised at the result of a case in the whole course of my practice.

I have also used the iodine ointment in cases of local oedema with the best effects. A short time since I attended an old woman affected with pleurodynia; she was of a debilitated constitution, and laboured under a rheumatic affection, which when removed, her instep and ankles became very much swollen and pitted on pressure. The ointment of iodine diluted was rubbed on the affected parts each day; in the course of a week the skin of the swollen parts presented large wrinkles, from the rapid absorption of the serous fluid, and

in a short time the swelling entirely disappeared.

There are many other remedies useful in dropsy, which I have not at present time to consider; in the few remarks that I have made on the treatment of this disease, I have adhered to the results of my own experience. In the course of our clinical labours I shall probably have abundant opportunities of investigating the different forms of this disease. What I have said this evening refers principally to that species of serous effusion which is the result of inflammatory action.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

DELIVERED

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE VII.

Maternal Influence on the Embryo—Monstrosities.

GENTLEMEN,—The mechanism of the perpetuation of our species is involved in impenetrable mystery. It occupied the attention of naturalists and physicians in all ages, but it still remains unknown. After all the hypotheses and systems of naturalists and physiologists, there is but one certain conclusion, that there must be a union of the sexes for the perpetuation of the species. In my work on Midwifery, I have given a full account of the ancient and modern theories of generation, and the conclusion drawn by all who have written on the subject from the time of Plato to the present, which is, that both sexes contribute to the propagation of the offspring. Both should be of the adult age, and of sound constitutions, and their moral and physical energies fixed upon the desired object. Conception is most likely to happen a few days after menstruation, when the womb has performed its function. Repose and tranquillity of mind during the first days after impregnation are proofs of a regular conception; and if the passions of the mother can deface or deform the infant, which is undecided, they can only do so in the first days of its existence, when it is passing from the ovary through the uterine tube, whence it may escape or be arrested, and the pregnancy become ovarian, tubal, or extra-uterine. It is maintained by almost all writers, that the moral and physical dispositions of parents are transmitted to their offspring; and therefore that healthful parents will generate healthful infants, and delicate or diseased parents, feeble and delicate infants. It is also an axiom, that procreation cannot be effected at the will or desire of the sexes, nor can the sex or beauty of the offspring be

determined. Every one knows that many persons anxious for children never have any, and some wish to have none, but have them. We cannot therefore assent to the hypothesis of our Gallic contemporaries, that "the sex of the offspring may be determined by the will of the parents." If this were true, the anxieties of those whose titles and estates are to become extinct, or pass into the possession of others, on account of the want of a male heir, could not exist. Nevertheless our French contemporaries, who manage these points better than ourselves, "describe the art of procreating the sexes at will (Millot); infants of spirit without passions (Robert); of beauty (Quillet), and sound and vigorous." Such are the reveries of this age of intellect, which are opposed to common observation and to numerous anatomical and physiological facts. MM. Jadelot, Legallois, and Gardien have completely refuted these ridiculous opinions. If the will or the imagination of parents could fix the exact moment of conception, the sex, beauty, and vigour of their offspring, there would never be ugly, delicate, or deformed children. Few women, I should suppose, could fancy deformed offspring; yet it is the common opinion, that marks and deformities are caused by the mother's imagination. If the mind of the mother could prevent such blemishes, I believe they would never happen. I shall examine the validity of this doctrine hereafter, and, I think, refute it. There are some other curious inquiries with regard to the sex of the foetus. Women in all ages as well as the present, felt, and do feel, great interest in endeavouring to ascertain the sex of the foetus, or infant, during pregnancy. Every woman wishes to know whether she carries a male or female; this is the case in all countries. In remote ages, inquiries were made of astrologers, soothsayers, sorcerers, fortune-tellers, empirics, and midwives. The Egyptians and Indians referred to the state of the heavens, and to the conjunction of the planets at the time of conception. The Greeks and other nations invoked the phases of the moon, and the ancient physicians were of course consulted. Hippocrates and Aristotle held, that a male was more slowly developed than a female, that pregnancy was more protracted, and that the mother enjoyed better health, when she carried a male infant. There are various ridiculous experiments proposed in the work ascribed to Aristotle, which is now in great circulation, and the standard authority with midwives and others, though a production only published more than a century ago by an empiric named Salmon. This production is erroneous from beginning to end, and is highly detrimental to morals and to human life. I need scarcely mention, that it is impossible to discover the sex of the foetus in the womb, or the moment of conception. MM. Viréy, Girou, Dugès, and Velpeau, incline to the opinion, that the sex

of the infant will be determined by that of the parent who enjoys the most prolific power at the instant of conception. According to MM. Alphonse Leroy, and Bailly, males are propagated by vigorous parents, and females by feeble and delicate. I think both these conclusions are erroneous. I have referred to the cases of some hundreds of my patients and acquaintances, and have ascertained in a vast number of instances that old men procreate male infants, though evidently less vigorous than their youthful and healthful wives; and delicate women have male children, though united to strong, athletic, and vigorous husbands. Some married persons have several sons or daughters in succession, though there is the greatest difference in the strength and constitutions of the parties.

The ideas of the ancients and some moderns on the influence of the right testis and ovary (male) and those of the left side (female), are perhaps false, because a woman and an animal with one ovary only have begotten male and female offspring. But there is no instance on record, at least as far as my researches enable me to judge, in which a woman or an animal deprived of one ovary, and a male wanting one testicle, corresponding right or left, have propagated offspring of both sexes. The absence of one ovary, the presence of both testes, and the generation of infants or animals of both sexes afford no evidence on the subject.

It is maintained by medical statistical writers that prosperity, salubrity of climate, high temperature, civilisation, liberty, misery, calamity, and epidemic diseases, such as cholera, typhus, influenza, plague, &c., have great influence on reproduction, and that more infants are born in temperate countries, where the arts, industry, and the sciences flourish, than under opposite conditions, and that scarcity and famine produce great changes in the population. (Villermé.)

According to the received doctrines on generation, both sexes contribute to the formation of the infant, which is denominated germ or embryo, during the first-three months of its existence, the fetus during the remainder of the term of utero-gestation, the infant at birth and for two years afterwards. The embryo adheres to the womb, which supplies it with the mother's blood for nine months; and the source of this supply is the placenta, or after-birth. The embryo or future infant is a living being from the moment of conception; though the law of this country holds it to be inanimate until after the period of quickening, which is about the fourth month and a half, and orders a pregnant woman before this period to be executed. This is a most erroneous and inhuman decision, but it is founded upon the ancient medical error of animate and inanimate infants. There is another grievous error in our laws, in referring to a jury of matrons the difficult question, whether "a woman be with child, and whether she be quick with child." There is not a question in the whole domain

of medical science, more difficult to be determined than this, as you will find by reference to any of the works on medical jurisprudence. There is a host of evidence adduced in confirmation of this statement in a learned essay on pregnancy in the *Cyclopædia of Practical Medicine*, by Dr. Montgomery, Professor of Midwifery in the Dublin School of Medicine. I have maintained in my work on Medical Jurisprudence, that a jury of infants or bed-lamites would be as competent as one of matrons to decide the question. A forcible proof of this position was lately afforded at the assizes, I think at Norwich, where a jury of matrons decided that a woman who pleaded pregnancy in stay of execution, was not quick with child. The counsel for the accused, Mr. Sydney Taylor, appealed to the judge, and argued that medical evidence only was adequate to determine the question at issue. The learned judge Mr. Baron Bolland, ordered three surgeons to examine the woman, who decided that she was pregnant of a living child, and the execution was stayed. Mr. Taylor, much to his credit, has published a letter in which he states that this case has put an end to the appointment of juries of matrons.

The embryo or infant is alive from the instant of conception, and is nourished by the blood furnished by the womb. Nature, ever wise and provident in her works, sends the blood into the cells of the placenta, whence it is absorbed by the extremities of the infantine vessels. The circulation of blood between the mother and infant in the womb is not direct or continuous, for were it so, whenever the circulation of the mother was accelerated by mental or corporeal exertion, it would destroy the embryo in the first hours or days of its existence, when it is a mere atom and only perceptible by the strongest microscope. All obstetric writers agree that the circulation between the mother and the infant is interrupted, and also that there is not a direct nervous connexion between them. Nerves have never been discovered in the placenta or its continuation the navel cord, which passes into the infantine abdomen. The mind of the mother, therefore, cannot have a direct influence upon the fetus, no more than the circulation of her blood. Mental and corporeal excitement may derange the function of the brain, nervous system, heart, and digestive apparatus; but such derangements have only an indirect effect upon the fetus in utero. It therefore follows that the imagination of the mother cannot mark or deform the offspring, for if it could, no infant would be perfect; because there never perhaps was a pregnant woman, who was not frightened, or who was free from longings during her condition; and yet how few deformed or disfigured infants are born. The imagination is excited in every case of pregnancy, there is a constant cause, but very rarely an effect. This is bad philosophy. Every obstetrician engaged in practice

has repeatedly known pregnant women, who had ungratified longings, who had been frightened by dismal objects, or had met with dreadful accidents or misfortunes, and yet their infants were perfect. We see this fact illustrated every day in this immense capital. Nevertheless, the belief is general among the middle and lower classes, and even among some medical practitioners, that the frights, longings, and imaginations of the mother can mark and deform the offspring; but this opinion is contrary to nature, reason, common observation, and medical science. I have known hundreds of instances in which women feared that their infants would be marked; but I never met with one case in which such anticipation was confirmed. The belief in this error is, however, of great antiquity.

The older writers supposed that certain positions, as lying on the right side after coition, would ensure a male, and on the left, a female; but the will has no power over fecundation. It is not in our power voluntarily to create the sexes, neither with respect to the number of children, nor with regard to their future physical or moral qualities. This is the most modern opinion of physiologists, and of course controverts the vulgar notion that the imagination of the woman can disfigure or injure the infant, an idea that clearly shows the low ebb of physical knowledge of former times, and the gross materialism with which the philosophy of the human mind was contaminated and degraded; a doctrine inconsistent with right reason, experience, and anatomical knowledge. The belief in the power of imagination is, however, of very high antiquity, as appears by the contrivance of Jacob, to increase the lambs, calves, and kids which were to fall to the share of Laban, (Gen. cxxx. 37, 39.) But the divine influence had interposed in that instance, and therefore it is out of the ordinary course of nature. The ideas of mankind, at this early age, on this subject, were vague and ill-defined. The popular opinion prevailed in Greece, and was sanctioned by Hippocrates and Galen. The Spartans had their pregnant women to gaze on pictures, or figures of Nereus, Narcissus, Hyacinthus, Castor and Pollux, and on the more youthful divinities. Hesiod and Hippocrates speak of imagination; Galen and Oppian on the force of mere vision. The doctrine was adopted by the Arabian physicians, Avicenna and others, and in time by the schoolmen of the twelfth and thirteenth, and by the physiologists of the fifteenth and sixteenth centuries. Albertus Magnus, an ecclesiastic, described the power of imagination, and said it arose from celestial influence. He enters on a long discussion on the influence of the planets on the foetus in the womb. These mysterious and extravagant notions were first imbibed by Thomas Aquinas, the angelic doctor, and made more unintelligible by a mixture with universals, substantials, elementary qualities, &c.; and these opinions were

received by the most eminent physicians of the age, even by Roger Bacon, Arnold de Villa Nova, and the Hon. R. Boyle, the distinguished philosopher and chemist. Fiennius, of Louvain, published a work on the subject, in 1608, and the greater part of the seventeenth century was remarkable for this imaginative philosophy, and its offspring—the gross credulity in the collection of all sorts of marvellous and prodigious stories. An unanswerable objection to all these stories is, that not one of them is sufficiently authenticated. Towards the end of the seventeenth century, even Stahl, Hoffman, and Boerhaave, believed in this doctrine. Van Swieten and Turner were also strong advocates in favour of this view of the subject. In the year 1716 M. Marcet wrote against it in the Transactions of the Society of Medicine, at Montpellier. He denied that there was either a direct vascular or nervous connexion between the mother and infant, and also that the infant could see or hear in the womb of the mother, as asserted by the Abbé Malebranche; and that although there are hereditary diseases, they are independent of the imagination of the mother. He ridicules the idea that James the First was terrified at the sight of a sword, because Queen Mary had been frightened, during pregnancy, by the murder of David Rizzio in her chamber; for he proves that the fears of the mother are generally discovered after the birth of the infant, and then laid hold of by the friends to explain the deformity. The best work against the imaginative doctrine, which I have seen, was published by Dr. Augustus Blondell, of London, in 1728; and he was opposed by Dr. Superville, a German, in the Transactions of the Royal Society of London, in 1740. This writer was opposed, in turn, by the celebrated Buffon, who contended that marks were more dependent on the fancy of others, as to resemblance, than of the mother; he explained the influence of change of season, and why marks on the skin were redder in summer. He maintained that it was as easy to suppose a hen on her eggs, who sees the neck of a cock twisted off, can produce chickens with crooked necks, as for a woman to bring forth a dislocated child, by seeing a man broken on the wheel. As to dislocations and fractures of infants before birth, the imagination could not cause them; but scrofula, syphilis, rickets, or molities ossium, may. The doctrine was also opposed by Eller, in the Transactions of the Berlin Academy, by Krauv and Røederer, at Petersburg, and most successfully by the illustrious Haller, in 1766. This latter eminent physiologist admitted that he saw marks that might arise from any cause capable of corroding the skin, which might, by a lively imagination, be transformed into fruits, mice, sparrows, flames, &c.; but most of them happen without any affection of the mind, or disorder of the female.

The case of Malebranche and others Haller

regarded as erroneous. No nerves pass directly from the mother to the fœtus, and hence no mental power can directly affect the latter. The question had been settled by Haller, sixty years ago, and was never doubted until 1825, when Sir E. Home opposed it in the *Philosophical Transactions*. Where is the instance that can be indubitably shown, in which any object that can act on the mother's imagination has unquestionably influenced the fœtus? Is it proved in the relation of cause and effect? In truth, we have in medicine more false facts than false theories. Sir E. detected nerves in the placenta, by the assistance of M. Bauer, of microscopic celebrity; but it is surprising that no other anatomist or physiologist should have observed the placental nerves to this time. It is rather extraordinary that these nerves should have eluded inspection, if they proceeded in a body from the placenta to the child; yet Sir E. found them in a preparation of a placenta belonging to Mr. Brookes, which had been in spirits for forty years.

The theories of the imaginationists have varied in every age; and it is impossible that experience can support such contradictory and different assertions. Thus the supporters of the doctrine are not agreed as to the person whose imagination is excited, when it is excited, or the exact extent of its influence. For example, Pliny was of opinion that the imagination of both sexes, male and female, was reputed to imprint or confound the similitude (book. vii. chap. 12). Others asserted that it was the fœtus that caused the longings; and where they have not been duly gratified, the wise women, thinking that the infant was in want, have supplied all deficiencies after birth, by making it suck a piece of roasted pork, as a certain panacea to supply all former disappointments. This custom still prevails among the vulgar, and no doubt is rather obscurely consonant with physiological science, with fair logical deduction, and with the due connexion between cause and effect. The variations of the power of the imagination, as to time, are very remarkable; some say it is effected at the moment of conception (Pliny, *op. cit.*); others, before quickening, that is between the third and fifth months, and that there is no danger afterwards; and others, that the imagination is most powerful after quickening. (Turner on Diseases of the Skin.)

If we examine the reputed cases detailed by Dr. Turner and others, we shall in every instance discover the credulity of the witnesses, the inconclusiveness of the evidence, and the absurdity and folly of the narrations. Thus, a woman in Italy longed for a lobster, and not being gratified, brought forth a lobster. Such is the story of Aldrovandus. There was a child said to be born in Normandy, in 1682, with horns and cloven feet, because his father, having represented a satyr on the stage, had connexion with his wife in his stage dress. (Zodiacus Martius.) Hildanus was informed

by Hornicæus, a physician of Frankfort, that a woman being frightened by a musket shot, brought forth a child with a wound in its back, as if made by a musket ball. I would ask, was this wound made by the imagination, and what stopped the bleeding? The Abbé Malebranche relates various incredible stories of this kind; one in which all the bones of the fœtus were broken in the womb, because the mother had witnessed the breaking of a male-factor on the wheel; another, where the child was born, resembling Saint Pius, as the mother had gazed on his picture. About the year 1700 a boy was exhibited in Moorfields, in this city, who had the word "Elohim," in Hebrew characters, round one iris, and "Deus" round the other. This deceit was managed by two thin pieces of glass, or artificial eyes. A child was lately exhibited in London, with the words "Napoleon Empeur" on each iris, and said to have been caused by the mother having cried over a French coin, which was left her by her brother. I visited this case, and aver that there was no letter whatever visible, but the usual appearance of the blue eye of an infant for the first three months. Malebranche asserts, that the infants in the womb see and hear, as their mothers, have the same passions, &c. I would ask, how can an infant, enclosed in the membranes, see without light; and surrounded by the womb, the membranes, and a considerable quantity of fluid, hear external sounds, without vibration of the air? The good father relates a case in which the bones were soft from imagination, the mother having witnessed the execution of a criminal; but will not mollities ossium, or softening of the bones, better explain such an occurrence? Hesiod recommends men not to cohabit with their wives after the latter returned from a funeral; but in this country people are not so fastidious or cautious, and pregnant women attend funerals; and although the mind is naturally depressed, we never hear of or observe a child marked with a coffin, scarfs, or white feathers. There is no truth whatever in the fabulous stories that Ethiopians have produced white children, or Europeans children perfectly black. There is good reason to suppose that there were other very solid and more legitimate causes to account for the phenomena. Bartholin relates the case of a woman who, in 1638, produced an infant with the head of a cat; but a flat nose, a short chin, and a few hairy moles would account for that sage report. The same writer describes a case where a rat was produced. How unfortunate it was that the cat happened not to be in the apartment! This writer also speaks of a woman who was brought to bed of two small fishes, with scales, which were no sooner born than they swam in the neighbouring lakes!! But the semen of one species of animals will not impregnate another; for if the converse of this held good, there would be an endless confusion, and no distinct generation.

One of Pope Nicholas's family (the *Usini*) brought forth a substance like a bear; but how very singular that the lady should be frightened by looking on her own coat of arms. I should not dwell on these absurd stories, had not Sir Everard Home lately attempted to revive this ridiculous doctrine.

Ludovicus Vives informs us, that a loose fellow, at Brabant, who personated the devil in a play, said he should have to do with his wife in his stage dress, which so frightened the poor woman, that she in due time brought forth an infant of a diabolical figure. An American woman is said to have brought forth a child with a wooden leg, and a ferule at the end of it, exactly similar to her husband's. Though physiologists assure us that the blood produces all the tissues in the human body, they have overlooked the power of its producing a wooden leg with an iron ferule. In this country the blood does not take on that action, as fathers with one leg produce infants with both natural,—neither of them cork, wood, or iron.

All these monstrous facts occurred in the sixteenth and seventeenth centuries, which were famous for superstition, ignorance, and credulity. A most singular illustration of the credulity of that era is afforded by a writer named Gofr. (Hegenitii *Itinerarum*, &c. 1630.) This traveller states that he saw a tablet in the church at Leusdown (Laudunum), about five miles from the Hague, with an inscription to the following effect:—that a certain illustrious countess, whose name and family are given, in the fortieth year of her age, brought forth, at one birth, in the year 1276, three hundred and sixty-five infants, all of whom were baptized by Guido the suffragan, who called the males "John," and the females "Elizabeth," all of whom with their mother died on the same day, and were buried together in the above temple. This happened on account of a poor woman who carried twins in her arms, which the countess held were not the offspring of one man, which incensed the mother, who prayed that she might have, at one birth, the same number of children as there were days in the year. No rational individual can credit this story, though it is attested with much plausibility, as will appear by the inscription itself, which I cannot help quoting.

"Laudunum sive Losdunum. In templo hujus pagi tumulus comitisæ, quæ uno partu trecentos sexaginta quinque infantes edidit. Pelves ex ære illic pendent cum hæc inscriptione.

"In dese twee Beckens syn alle dese Kinderen ghedoopt."

"Quin et historia ibidem duplici sermone Latino et Belgico tabulæ inserta legitur. Latina sic incipit, uti quidem juxta tenorem formæ authenticæ huic bonâ fidē memoro.

"En tibi monstrosum nimis et memorabile factum,
Quale nec à mundi conditione datum."

"Margarita Hermanni Comitissæ Henenbergiæ, uxor, quarti Florentii Comitissæ Hollandiæ et Zelandiæ filia, Gulielmi Regis Romanorum ac postea Cæsaris seu gubernatoris Imperii, atque Alitheisæ Comitissæ Hanoniæ soror. Cujus patruus Episcopus Trajectensis, avunculi autem filius Dux Brabantis et Comes Thuringiæ, &c. Hæc autem illustriissima Comitissa annos quadraginta circiter nata, ipso die Parsceves nonam, circiter horam, anno millesimo ducentissimo septuagesimo sexto, trecentos et sexaginta quinque enixa est pueros, qui prius à Guidone suffragano Trajectensi omnes in duabus ære pelvibus baptisati sunt; quorum masculi quotquot erant 'Johannes,' puellæ autem omnes 'Elizabethæ' vocatæ sunt, qui simul omnes cum matre uno eodemque die fati concesserunt, atque in hoc Laudunensi templo sepulti jacent. Quod quidem accidit ob pauperculam quandam foemina, quæ ex uno partu gemellos in ulnis gestabat pueros, quam rem ipsa Comitissa admirata dicebat id per unum virum fieri non posse, ipsamque contumeliose rejecit; unde hæc paupercula animo perturbata ac perculsa mox tantum prolium numerum ac multitudinem ex uno partu ipsi imprecabatur, quot vel toties anni dies numerentur. Quod quidem præter naturæ cursum, obstupendâ quâdam ratione ita factum est, sicut in hac tabula in perpetuam hujus rei memoriam ex vetustis tam manuscriptis quam typis excusis chronicis breviter positum et enarratum est. Deus ille ter maximus hæc de re suspiciendus, honorandus, ac laudibus extollendus in sempiterna secula.—Amen.

"Hæc lege, mox animo stupefactus lector abibis."—*Op. cit.*

It is difficult to imagine how such a tale as this could be palmed upon the public in any age or country, but is as well worthy of credit as the narrations about monstrous births related about that same period. This countess must have been of an incredible size during pregnancy. According to the ordinary weight of infants at birth, she would have carried more than a ton burden; and lastly, only fancy the size of a woman three hundred and sixty-five times larger than one at the end of pregnancy! Fables as incredible occur in our own days. I shall give you an example or two. I attended a premarious lady five years ago, whose mind was full of all kinds of marvellous notions regarding parturition; and whose nurse had gravely told her, that a woman in the immediate vicinity was delivered a few days before of a demon. I questioned the nurse on this sage report, and requested to know the address of the woman who brought forth such a frightful object; but she, as in all such cases, had merely heard it accidentally, and knew nothing concerning it. Another lady aborted about the third month, on account of a fright she received in one of the markets by a rat running close to her feet. She was greatly alarmed about the appearance of the abortion. A member of the profession called on me in great tribulation, as he feared his wife would

be delivered of an infant with a hare-lip, "for she had seen a hare the day previously." I dissipated his groundless fears, and convinced him of the absurdity of the notion he entertained. He called on me at a future time with joy on his countenance, to inform me that his wife had been delivered, and the child was perfect. It has been recorded, that infants have been marked with the figures of frogs, mice, rats, &c.; but thousands of women have been frightened by these vermin, and no mark has appeared on their infants. How often do we find marks, when the mother can recollect no fright to account for them? Those who are imaginationists forget that women pass through pregnancy contrary to their wishes; and, notwithstanding all mental, medicinal, and mechanical means wickedly and designedly tried to effect abortion. If the imagination could convert the fœtus into a shapeless mass, their wishes could be easily accomplished.

Again; the nutrition and growth of the infant go on according to the laws of nature, whether the woman wishes or not. It is also out of the mother's power to choose a boy or girl; to have one or more children at a birth; to cause the infant to be fair, dark, large or small, weak or strong, or to give it her own or the father's features. If, then, women cannot, by imagination or will, promote or impede conception, how can any one believe, without derogating from the power and wisdom of God, that they can disfigure the infants, and injure the works of nature? Is it not absurd to suppose that the mother has more influence over her child than over her own body? The idea is preposterous. If she cannot, by the strength of her imagination, make any mark on her own body, or change the figure, situation, quantity, and number of her own limbs, why should we believe she can do so to the body of the infant? Is it not silly and ridiculous to think that if the affrighted mother apply her hand to any part of her body, which may be done accidentally and undesignedly, this can affect the same part of the infant? Does she mark that part of her own body by such application of the hand? (chirapsy.) But the child hears and sees, and feels the passions of the mother. How can this happen when there is no nervous connexion between the mother and infant? Surely every obstetrician has observed, on dividing the navel-string, that the child suffers no pain whatever, neither does the mother. And can nerves be divided in any other part of the body without pain? Again; how can the mother communicate her thoughts to the child, when her soul is distinct from that of the infant? That marks and deformities frequently happen cannot be denied; but they can be accounted for in a much more scientific and natural manner than by the influence of the mother's imagination.

Why should we be surprised at some irregularities on the skin and other parts of the body, when we observe the same happen to

vegetables, though incapable of imagination? They have their moles, their hairy parts, their discolorations, their excrescences, their unnatural shapes, which resemble animals and other bodies, and all without the help of fancy. There are many deformities never referred to the imagination, as the irregular conformation of the viscera. Is the whole empire of the microcosm, or world of the human body, so divided between nature and imagination, that one governs the internal and the other the external parts? We ought to be little amazed, at the deformities, when we consider the wonderful uniformity that exists among all living creatures. We should remember that the rudiments of all animals are infinitely small, and composed of an infinite number of minute parts, which the least shock may put out of order; and yet they remain whole and entire, except in a few extraordinary cases, which we can readily account for by the following reasons; firstly, the variety of particles, and of their combination; secondly, the distempers of the children in the womb; thirdly, the interrupted developments of some parts in the children; fourthly, force and violence upon the body of the infant; and lastly diseases from inheritance.

The variety of particles, and of their combinations, is the first cause of marks in children. If we examine ever so many bones of the same kind, and as near as possible of the same kind, we shall find a vast difference in their shape, in their cavities, in their extremities, and surfaces, and in the number, situation, and disproportion of the foramina or holes through which the blood vessels pass. This proves that the arteries and veins have not the same diameters, situation, or branches, in all individuals, a fact known to every anatomist; thus the particles which make up one body, differ from those of all others. This accounts for the several irregularities and deformities of different bodies, and for the congenital diseases of new-born infants. The diseases of children in the womb are numerous, and known to all practical obstetricians; and these are causes of defects, marks, and deformities.

The excessive development and unnatural growth of any of these parts will cause deformity, and is of frequent occurrence. The same development accounts for deformities on the external surface of the body; thus the various tumours.

Every part of an infant in the womb may be more or less diseased or defective. We often observe cataract, amaurosis, aneurisms, varices, jaundice, hydrocephalus, and various other congenital defects in infants; but who could seriously think that any of these defective diseases, these marks and deformities, depended on the imagination of the mother. The passions or imaginations of the mother can only act in an indirect manner on the infant, by debilitating the mother only; but all marks, deformities, and diseases of the infant

depend upon unnatural development of certain particles or parts which compose its body. The parts of the fetus are delineated in the ovum, but they do not increase in the same proportion; and the increase of some parts being prevented, will induce deformity. Force or violence upon the body of the fetus, or pressure of the womb by tight lacing, will cause deformity in the infant. Dr. James Augustus Blondel, about 1728, published a curious work on this subject, which was the best that had appeared against the power of the imagination of the mother. He maintains, among many other original and interesting opinions, that the rudiments of all plants and animals now existing, have existed from the creation; and that there is no new creation or equivocal generation. He contends, that there is no child born but whose lineaments have existed somewhere since the first creation, and in that somewhere, are liable to many vicissitudes. This somewhere was the primitive ovum, which had several ova within one another; and that, although there is no transmigration of soul, there is of body, and that each fetus has been successively in different women.

That the ovum, undergoing so many revolutions, may receive some damage, as all these mothers must have been liable to bruises, cuts, and wounds, to many diseases, scrofula, consumption, cancer, &c.; and therefore, that infants must be affected with various defects and diseases. He contends, that the largest oak has been in a small single acorn; and that a single acorn not only contains the oak, but also all the trees and acorns which shall be produced from thence successively, as long as the world lasts. If we look back to first causes, we should readily perceive the force and authenticity of these opinions; for it is manifest that the whole human race must have existed in the first of the species.

At our next meeting I shall describe the hygiene relative to Pregnancy, Parturition, and the Puerperal State, together with that of Infants.

WRIGHT ON CARDIAC PATHOLOGY.

Carditis and Pericarditis.

F. Antony, a female, aged about fifty, was admitted into the Baltimore alms-house in October, 1831, affected, as had been supposed, by pneumonic catarrh, now in a somewhat chronic stage. She had cough of some weeks' duration, without pain of the breast, and only slight impediment of respiration. A considerable degree of mucous rattle was discoverable in her breathing; expectoration trifling, of common pituitous matter. There was no fever; pulse soft, rather small, in-

dicating great debility. Personal appearance in this case was indicative of naturally robust constitution. The woman was above the middle size, still muscular, and reported herself to have enjoyed general good health, without any former serious illness, and had for many years past performed laborious services, chiefly as a cook; present indisposition, altogether, of three weeks' duration.

The information obtained of the patient respecting the early circumstances or symptoms of her present illness was partial and uncertain, fitted rather to obscure than explain the cause or condition of her sickness at this moment; she was either unable or unwilling to give any consistent or intelligible account of her recent state; appeared to think her illness slight, and was impatient of inquiries on the subject. The signs of danger were now manifest; evidences of serious impairment of vital power were revealed, both in the respiration and the pulse; the first was imperfectly performed, and attended by symptoms of pulmonary infiltration to an extent which must greatly embarrass the office of the lungs; the latter was deficient of tone, in a degree betraying unsafe diminution of that nervous influence by which the heart's action is sustained. Brain embarrassment was the interpretation to which the symptoms appeared to point. Diagnosis—congestion, vascular engorgement of the membranes, more especially about the tuber annulare and medulla oblongata; cerebral serosity in excess, and increasing. Prognosis—death in a few days by effusion.

The patient prostrated more rapidly than was anticipated, and died on the night of the second day after admission. There was no convulsion, nor any violent tumult before death; neither did coma or insensibility supervene, the patient continuing conscious and intelligent as long as she lived. The difficulty of respiration augmented gradually after admission, unattended by cough, but with constant

increase of the pulmonary roushus before noted, showing progressive decay of that particular innervation on which the lungs mainly depend for their vital endowment.

Examination.—The contents of the thorax free from any signs of recent inflammation; lungs natural, neither reddened nor hardened in any appreciable degree; serous membranes pale, and looking natural; partial adhesions and thickening in places, showing traces of former phlogosis; some pleuro-pulmonary serosity, apparently old. In the head was found large excess of surface fluid, quantity greatest toward the base, (cerebro-spinal dropsy;) membranes of the brain very much tinged by patchy redness; colour highest over posterior lobes. The vascular plexus about the pons was highly engorged; arachnoid of cerebellum and medulla oblongata pink-red; aqueous accumulation large around the pons, crura cerebri and cerebelli. The ventricles exhibited only small serosity; substance of the brain apparently natural.

The heart of this subject was taken out for examination, in consequence of apparent uncommon density of its envelope. The pericardium proved on incision to be one-eighth of an inch in thickness, and so hardened in texture as to cut like wet leather. This unnatural thickness and solidity of the bag of the heart was uniform, or the same every where; and when it was laid open fully, its interior, or cavity, presented a singular spectacle. The apex of the heart cohered firmly to the bottom of the sac, and every part of its body and sides was tied to the interior of the pericardium by fibrous interlacements, of considerable length, but so close and strong as to present the appearance of a dense network, that could not be broken down by the fingers by any common force. The cavity of the bag of the heart, in fact, was a perfect web of fibrous or filamentous formations, about the size of large sewing cotton, crossing each other in every direction, and filling almost completely the naturally free

space between the heart and its capsule. The body of the heart itself was unusually pale, almost white, and instead of its proper smoothness, its exterior was overspread and roughened by indentations very much resembling the pits of small-pox, apparently the remains of extensive puncturated ulcerations.

Remarks.—All the appearances about the heart, noted in examination, were plainly effects of some ancient inflammation, which from the consequences, could hardly have been slight. It is manifest that both the heart's substance and its investing sac must have equally participated in the morbid actions which bound them together by such a multitude of preternatural ligaments. Yet from the patient's account of herself, her report of general good health, and almost total exemption from sickness until very recently, the laborious nature of her occupation, regularly followed until the commencement of her late illness, and from her personal condition, fleshy and well nourished, it would appear, first, that the time and circumstances of the morbid development in the textures affected, was not marked by corresponding signs of illness or danger; and secondly, that the great lesion of structure betrayed by these parts, had not afterwards materially interfered with the important function performed by the heart, and did not sensibly abridge the comfort, or impair the health of the individual, to whom had occurred a change replete in contemplation with so many probable and serious evils.—*Amer. Jour. of Med. Science, May, 1833.*

DR. R. HUNTER ON FUNCTIONAL
DISEASES.
OF FEVER.

Is fever an assemblage of disordered functions; or is it dependent uniformly on some structural cause? The question is of great importance, and deserves a more particular examination than we can allot to the subject. The

definitions of fever, as given by our most learned nosologists, would lead to the first conclusion, and the investigations of our ablest pathologists tend decidedly to the second. The subject must ultimately be decided by a reference to dissection. Many pathologists attribute fever to a local cause—to inflammation of some vital organ, as the brain—spinal cord—lungs, or intestinal canal, &c.; and although a great discrepancy of opinion exists regarding the uniform seat of this morbid affection, facts are sufficiently numerous to prevent us from falling into the error of attributing all febrile ailments to a cause purely functional. I have no reason to think that fever arises from a morbid state of any one vital organ, because the symptoms are never exclusively referable to one organ, but indicate a morbid condition of the whole system. Pain in head and back—acceleration of pulse, and irregular respiration—thirst, with unnatural urinary and alvine evacuations—increased or diminished heat, with irregular cutaneous discharges—torpidity of all the senses, and deficiency of muscular power. These symptoms exist in a greater or less degree in every fever, and consequently no morbid condition of any one organ can explain all the phenomena. That inflammation frequently exists in some part of the body during fever, must be conceded; but that inflammation of *one* organ is the proximate cause of fever, I cannot admit, for the following reasons:—1st, Inflammation of any one vital organ does not produce a train of symptoms similar to fever in its intermittent, remittent, and continued form. 2nd, In fatal cases of fever decided marks of inflammation are frequently not to be found. Did time permit, it would not be difficult, I think, to show that fever consists in a morbid state of the capillary vessels of the whole body—a morbid condition of tissue which leads, in the first place, to congestion and accumulation, and afterwards, according to external circumstances or state of

the constitution, to inflammation, or even disorganisation of some of the textures affected. Let us suppose that fever may arise both from cold and contagion, we can easily conceive that these causes could act mechanically both in a direct and indirect way on the living textures. That they could affect the capillary vessels to which they are directly applied, can scarcely be doubted, and the affection could then be supposed to extend itself over the whole body. In those cases of fever which I have had an opportunity of examining, although in some I have been able to discover no trace of inflammation, in no instance have the capillary vessels of the internal organs been free of congestion; and in some cases I have found them gorged with blood to such a degree, as obviously to render the organs incapable of executing their functions. What may have been the cause of this congestion I cannot tell. It is easy to say that it arises from a want of action in these vessels, and thus connect the disease with a functional cause. But where is the proof of this assertion? It is still a disputed point among physiologists whether the capillary vessels have any action or contractile power, and when we have a palpable change of texture in all such diseases, and a change of texture capable of explaining all the attendant phenomena, why should we hunt after causes which lie beyond the scrutiny of our senses, and which may have no existence save in the imagination of the investigator?

Lastly; when a man dies without any apparent disease, as from pure old age, we might be inclined to view death, under these circumstances, as a simple cessation of action, or as a functional disease. Death from pure old age is, I conceive, a very rare occurrence, but when it does take place, it is, in my mind, clearly from a structural cause. At the early periods of life all the textures of the body are soft and pliant; as age advances, the textures become more rigid; and in extreme old age when the eye becomes

dim, all the senses more torpid, and the muscles refuse to obey the impulses of volition, with what show of reason can we maintain that all this arises from functional derangement? Do we not find an obvious change of structure in almost every organ of the body, and a change of structure so palpable, that it cannot be mistaken? The changes of the *outward* character of the man are so well marked, that we can deduce from them the age of the individual. Corresponding changes take place in his *internal* organs. As the individual advances in years, the structure imperceptibly changes, till at last it is no more capable of evincing the phenomena of life than the rudest block of inanimate matter, or the piece of clay moulded by the hands of the artist into the likeness of humanity. There is a period beyond which an animal body cannot survive. Constituted as we now are, a corporeal immortality is physically impossible, and this arises not from any thing necessarily mortal in the vital principle, surely, but is attributable alone to the inevitable changes or deteriorations that take place in the corporeal structure.

Enough, I presume, has been said to show that the above reputed functional disease is really of a structural kind, and that diseases purely functional cannot exist. The more pathological anatomy is known, the more striking will the truth of these observations appear; and till that department of medical science is more studied than it is, medical language must remain ambiguous and incorrect, and medical practice unsettled and empirical.—*Glasgow Med. Journ.*

Review.

BRIDGEWATER TREATISES.

The Hand, its Mechanism and Vital Endowments, as evincing Design.
By SIR CHARLES BELL, K.G.H.,
F.R.S. L. & E.

SEVERAL of our numerous readers cannot be aware of the cause that led

to the publication of this work. It is our pleasing duty to give them correct information. The Right Hon. and Rev. Francis-Henry, Earl of Bridgewater, by his last will and testament, bearing date Feb. 25th, 1829, directed that certain trustees, whom he named, should invest in the public funds the sum of 8000*l.*, (Oh, that we had many noblemen like him!) with accruing dividends thereon, to be held at the disposal of the President of the Royal Society of London for the time being, to be paid to the person or persons appointed by him, who would publish 1000 copies of a work—“*On the Power, Wisdom, and Goodness of God, as manifested in the Creation; illustrating such work or works by all reasonable arguments; as for instance, the variety and formation of God’s creatures in the animal, vegetable, and mineral kingdoms, the effects of digestion, and thereby of conversion; the construction of the hand of man; and an infinite variety of other arguments; also discoveries, ancient and modern, in arts, sciences, and the whole extent of literature.*” He desired, moreover, that the profits arising from the sale of the works so published should be paid to the authors.

When this will was executed, that truly scientific and admirable character, DAVIES GILBERT, Esq., was President of the Royal Society; and he, with that integrity which ever characterised him, requested the assistance of His Grace the Archbishop of Canterbury and of the Bishop of London, in determining upon the best mode of carrying into effect the intention of the testator. Acting upon their advice, and with the concurrence of a nobleman immediately connected with the deceased, the President appointed the following eight gentlemen to write separate treatises on the different branches of the subject proposed by the benevolent testator.

The REV. THOMAS CHALMERS, D.D., Professor of Divinity in the University of Edinburgh,—“*On the Power, Wisdom, and Goodness of God, as manifested in the Adaptation of*

External Nature to the Moral and Intellectual Constitution of Man."

JOHN KIDD, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford,—*"On the Adaptation of External Nature to the Physical Condition of Man."*

THE REV. WILLIAM WHEWELL, M.A., F.R.S., Fellow of Trin. Col. Cambridge,—*"Astronomy and General Physics, considered with reference to Natural Theology."*

SIR CHARLES BELL, K.H., F.R.S.—*"The Hand: its Mechanism and Vital Endowments as evincing Design."*

PETER MARK ROGET, M.D., Fellow and Secretary of the Royal Society,—*"On Animal and Vegetable Physiology."*

THE REV. WILLIAM BUCKLAND, D.D., F.R.S., Canon of Christ Church, and Professor of Geology in the University of Oxford,—*"On Geology and Mineralogy."*

THE REV. WILLIAM KIRBY, M.A., F.R.S.,—*"On the History, Habits, and Instinct of Animals."*

WILLIAM PROUT, M.D., F.R.S.,—*"On Chemistry, Meteorology and the Function of Digestion."*

His Royal Highness the Duke of Sussex, the present President of the Royal Society, intimated a desire that no delay should take place in the publication of the treatises above mentioned; and therefore it was unanimously resolved, by a numerous meeting of the Society, that the treatises should appear as soon as they may be ready for publication.

It is highly gratifying to record such a munificent bequest as the above for so laudable a purpose as diffusing, in the most extensive manner, the brilliant lights of religion and philosophy. Many learned and scientific members of the peerage, as well as of the upper ranks of society, in this country, have, from age to age, encouraged and promoted the greatest of all knowledge to man—the consummate wisdom, power, and benevolence of the Omnipotent Author of all things, and the gratitude

that man owes to his Maker and best benefactor. These treatises elucidate the wisdom and design of the whole creation, and render them intelligible to every one arrived at the age of reason. They are eminently calculated to inspire the human mind with the greatest veneration for the great Architect of the universe. Of these excellent works, that by Sir C. Bell claims our especial attention. It is purely physiological, and treated so familiarly, that every one can comprehend it. We shall insert a few extracts to show the manner and style in which it is executed.

After some observations on the complexity of animal organisation, the celebrated author observes:—

"These views lead us to another consideration, that the complexity of our structure belongs to external nature, and not of necessity to the mind. Whilst man is an agent in a material world, and sensible to the influence of things external, complexity of structure is a necessary part of his constitution. But we do not perceive a relation between this complexity and the mind. From aught that we learn by this mode of study, the mind may be as distinct from the bodily organs as are the exterior influences which give them exercise." p. 7.

This extract very clearly shows that Sir Charles Bell is no phrenologist, no materialist who would make man a vile and perishable insect. Every sentiment he utters accords with religion, reason, and physical science. He illustrates the most difficult points in human and comparative anatomy; and shows the harmony and design in the animal creation. Like Dr. Arnott, he sees nothing but perfection in all things.

"If the child upon the parent's knee is unconsciously incurring a debt, and strong affections grow up so naturally, that nothing is more universally condemned than filial ingratitude, we have but to change the object of affection to find the natural source of religion. We must show that the care of the most tender parent is in nothing to be compared with those provisions for our enjoyment and safety, which it is not only beyond the ingenuity of man to provide, but which he can hardly comprehend while he profits by them.

"If man of all living creatures, be alone capable of gratitude, and through this be

capable also of religion, the transition is natural, since the gratitude due to parents is abundantly more owing to Him 'who saw him in his blood, and said, Live.' p. 9.

The illustrious author displays in every paragraph, that inimitable comprehensiveness of knowledge and information which has ever characterised the eminent physiologist and the christian. During our editorial and literary career, we have not read a work whose perusal has given us more pleasure. It instructs while it amazes the mind, and excites the profound admiration of man, in learning the consummate wisdom and unbounded benevolence of the Author of all things. If Sir Charles Bell had never published another work, his name would pass down to the latest posterity as one of the greatest biologists of the past or present eras. The information contained in this production is adapted to the commonest capacity, and will be received with delight by every one blessed with reason and common sense.

The author concludes a well-written, modest, and sensible introduction in the following terms:—

"In the following essay I shall take up the subject comparatively, and exhibit a view of the bones of the arm, descending from the human hand to the fin of the fish. I shall in the next place review the actions of the muscles of the arm and hand; then proceeding to the vital properties, I shall advance to the subject of sensibility, leading to that of touch; afterwards I shall show the necessity of combining the muscular action with the exercise of the senses, and especially with that of touch, to constitute in the hand what has been called the geometrical sense.

"I shall describe the organ of touch, the cuticle and the skin, and arrange the nerves of the hand according to their functions. I shall inquire into the correspondence between the capacities and endowments of the mind, in comparison with the external organs, and more especially with the properties of the hand; and conclude by showing that animals have been created with a reference to the globe they inhabit; that all their endowments and varied organisations bear a relation to their state of existence, and to the elements around them; that there is a universal plan, extending through all animated nature, and which has prevailed in the earliest condition of the world; and that finally, in the most minute or most comprehensive study of those

things we every where see prospective design." p. 15.

From the previous expression of our opinion of the manner in which the author of this work has elucidated the arduous and most difficult task, very properly assigned to him we need not state, that he has treated every part of the subject in the ablest manner. It is a matter of deep regret to us, that our arrangements as weekly journalists prevent us from making more copious extracts; but the work is so interesting, so instructive, so valuable, that were we at liberty we should most cheerfully transcribe the whole of it into our pages.

ROYAL COLLEGE OF SURGEONS IN LONDON.

In pursuance of a resolution of the council, on the 29th of January last,

"That an exposition of the state of the College be from time to time made to its Members,"

The Council publish the following Statement:—

The Corporation of Surgeons, established as a distinct body, by Act of Parliament, in the year 1745, having become dissolved in consequence of an accidental informality in their proceedings, the present Royal College of Surgeons was founded in the year 1800 by His Majesty King George the Third, for the advancement of Surgery, for the examination of surgeons in the army and navy, and of other individuals who might wish to engage in the surgical profession.

The reputé in which the corporation was held appears to have been so limited, that a large proportion of the practitioners throughout the kingdom had undergone no examination, and had not even a nominal connexion with it. The inheritance derived by the College from the corporation was as follows:—10,135*l.* 7*s.* 5*d.*, 3 per cent. consols; 1233*l.* 15*s.* 0*d.* due from the City of London for the Hall in the Old Bailey; 2862*l.* 16*s.* 7*d.* in Exchequer bills and at the banker's; the house in Lincoln's Inn Fields, which then occupied one half of the site of the present premises, and a rent charge of 16*l.* per annum on premises in Snow-hill, bequeathed by Mr. Gale for the endowment of a Professorship of Anatomy. There were no certain funds of any other description, for defraying the expense of maintaining the great national collection purchased by Parliament of the executors

of Mr. John Hunter, and which the College now holds in trust for the public.

When the College received its charter from the crown, it derived no assistance of any kind from the other branches of the legislature: the charter was simply permissive, allowing the Court of Examiners to examine those who might voluntarily present themselves, but giving them no legal authority whatever, to compel practitioners in surgery to obtain their diploma, or to prosecute those who took upon themselves to practise without it. The College, therefore, possessing no other influence than that of opinion, was left to rest altogether on its own character. Under these circumstances, it would never have advanced to its present state of prosperity, if it had failed to obtain the confidence of the profession and the public; and the best proof that it has succeeded in this object, is to be found in the increased and increasing number of the members. In the first two years after the establishment of the College, the diploma was granted to 300, and in the last two years to not fewer than 770 members.

Although the College derives an important accession to its scientific character, from the possession of the Hunterian collection, its preservation and public uses have been a source of great expense to the institution.

The sum of 27,500*l.* obtained from parliament having been insufficient for building the Museum, an addition, amounting to nearly as much, was supplied from the funds of the College. But independently of what has been laid out on the building of the Museum, about 36,000*l.* have been expended on its contents. The council have always regarded the charge of the collection as one of the most important trusts of the College; and they believe they have best performed their duty by sparing no expense which might tend to make it as complete as possible.

Thirty lectures are delivered annually in the theatre of the College by two professors appointed by the council. To these the members of the College are admitted by right, and the senior students of the metropolitan hospitals by courtesy.

The library, collected within the last six years, and comprising the most valuable works in medicine and surgery as well as in general science, is open to the members of the profession and other scientific persons, on the most liberal conditions.

Notwithstanding the large demands made upon the funds of the College by the maintenance of the collection, by the formation of the library, and by the management of the general business of the institution, the annual expenditure has hitherto been kept within the limits of its income, so that a considerable funded property has gradually

accumulated, which is now at the disposal of the council, to be applied, as opportunities may occur, for the advancement of the sciences connected with surgery.

The following are more detailed statements, relating to the Museum, Library, and finances of the College.

MUSEUM.

By a vote of parliament, 13th June 1799, the sum of 15,000*l.* was paid for this noble collection; and grants amounting to 27,500*l.* were subsequently voted for the erection of a building suitable for its reception.

Stupendous as this collection appears when it is recollected that it was the work of one great mind, yet in the lapse of years it has been found that many chasms were left to be filled up by future labours and researches.

The Museum comprehends systematic series of specimens and preparations illustrative of animal and vegetable structures in healthy and morbid conditions.

Each series was originally commenced by Mr. Hunter, but many valuable additions have been made subsequently to his decease.

Subjoined is a detail of the present state of the Collection, comprising a summary of the original preparations, and of the additions in the respective departments of the Museum; from which it will be seen with regret how much the want of space precludes a due display of the valuable specimens.

I. *Physiological Series, or Natural Structures from the Animal and Vegetable Kingdom, in Spirit.*

Hunterian Preparations	3745
Additional Preparations	527
	— 4272

The whole of this series is displayed in the gallery of the Museum. It is that which came into the possession of the College in the most complete state, and to which Mr. Hunter appears to have devoted the greatest share of his attention.

The Catalogue of this series, authenticated by the revision of the founder, consists of quarto fasciculi containing manuscript prefaces and introductions explanatory of the several divisions, with general observations on the functions they were designed to illustrate. It comprised descriptions of about a fiftieth part of the series, whereas the portion of the catalogue now printed contains descriptions of about one fifth part of the whole.

II. *Natural Structure of Animals and Vegetables, not osteological, dry.*

Hunterian	. . . 617
Additional	. . . 128
	— 745

The printed catalogue of this division contains both the Hunterian preparations and the additions.

III. *Osteology, Human and Comparative.*

Hunterian	. . .	963
Additional	. . .	973

— 1936

Of these specimens about a fifth part only is displayed. The catalogue of this division is printed. In the basement of the Museum are upwards of 400 boxes, containing either the entire skeleton in a separated state, or portions of the skeletons of animals dissected by Mr. Hunter. These, from want of accommodation, have never been displayed or catalogued.

IV. *Natural History, in Spirit.*

Hunterian	. . .	1743
Additional	. . .	355

— 2098

This series appears to have been designed to convey an idea of the natural affinities of the animal kingdom in an ascending scale. The printed catalogue includes the *Invertebrata*, named principally according to the nomenclature of Cuvier, but retaining the Hunterian arrangement. This division is regarded as a preliminary to the physiological series.

V. *Natural History, dry.*

a. *Stuffed Animals.*

Hunterian	. . .	87
Additional	. . .	13

— 100

b. *Dry Specimens of Insects, Shells, Zoophytes.*

Hunterian and additional about 1000
No catalogue of these exists.

VI. *Fossils.*

Hunterian	. . .	1215
Additional	. . .	200

— 1415

There is a manuscript catalogue of this series with an introduction by Mr. Hunter.

The specimens are chiefly contained in cubes on the floor of the Museum, but the present accommodation does not admit of their proper arrangement and display.

VII. *Pathological Preparations, in Spirit.*

Hunterian	. . .	1084
Additional	. . .	308

— 1392

The catalogue of the Hunterian portion is printed, and the preparations are arranged on the left side of the floor of the Museum.

VIII. *Pathological Preparations, dry.*

Hunterian	. . .	625
Additional	. . .	95

— 720

This series had originally the most perfect explanatory documents of any in the Collection from the pen of Mr. Hunter, who bestowed great pains on its arrangement, preparatory, it has been supposed, to a work on the "Diseases of Bone." There is a printed catalogue of the Hunterian specimens, which are contained in drawers beneath the north platform.

IX. *Calculi and Concretions.*

Hunterian	. . .	536
Additional	. . .	1245

— 1781

About half of this series is displayed in cases on the floor of the Museum. A manuscript catalogue of the whole is completed, but the chemical composition of many specimens remains to be ascertained.

X. *Monsters and Malformations.*

Hunterian	. . .	218
Additional	. . .	127

— 325

There is an original catalogue of this series containing a classification of monsters by Mr. Hunter; according to which they are now arranged in the printed catalogue.

In addition to these are about 150 miscellaneous specimens, including casts, surgical instruments, &c., chiefly additions, and a collection of drawings and oil paintings, amounting to about 1000.

Besides the boxes of skeletons, before mentioned, the basement contains about 1520 store specimens, chiefly donations.

Of the preparations in spirit, a total of 8087, about three fourths are capable of being arranged and displayed in the present Museum. Of the dry preparations, a total of 7697, not more than one seventh part can be displayed, and even this proportion cannot be usefully arranged; so that little more than one half of the entire collection is at present capable of being exhibited to advantage.

Some room may be gained by new arrangements, and also by clearing the Collection of specimens of great bulk and little value; but it is evident that no measure, short of an addition to the actual capacity of the Museum, will be effectual for the purpose of usefully displaying the present Collection, and providing adequately for its increase. This subject has long occupied the deliberation of the Council, and its paramount importance will not fail to ensure their unremitting attention.

In proof of their sense of obligation to the father of his present majesty, by whose gracious favour the College was appointed the depository of this great national trust, the Council refer with satisfaction to a liberal expenditure for the due preservation and continual augmentation of the Collection; to its suitable display, so far as the building, erected for this special purpose, permits; to the endowments of professorships for its elucidation; and to the institution and encouragement of prize dissertations, some of which have proved valuable contributions to surgical literature.

Finally they refer to the formation and advanced state of the Catalogue, a work of peculiar difficulty, not only on account of

the defective state of the manuscript documents authenticated by Mr. Hunter, but from the scantiness of information respecting numerous specimens. Of this important work, now in steady progress towards completion, the following parts have been printed:—

1. Series of Pathological Preparations, in Spirit.

2. Series of Pathological Preparations, in a dry state.

3. Series of Comparative Osteology.

4. Series of Dry Preparations, not Osteological, in Comparative Anatomy.

5. Series of Monstrosities and Malformations.

6. Series of Exterior Natural History, in Spirit:—comprising altogether 708 pages in quarto.

A more elaborate Catalogue of the two first subdivisions of the physiological series, including the organs of locomotion and digestion, accompanied by explanatory notes and illustrated by engravings, will be published in October next.

The illustration from time to time of rare specimens and of such portions of the several series as are little known, by means of accurate engravings and descriptions, is already commenced in the memoir of the *Nautilus Pompiilus*.

The Museum affords an inexhaustible fund of information to the student of natural and medical science, and the Collection, taken as a whole, may be regarded as unequalled. No one who makes himself familiar with its treasures and is endowed with a philosophical spirit, will quit it without deriving a powerful stimulus to his anatomical studies, and discovering many interesting paths by which that spirit may be gratified.

It is open to members, and to visitors properly introduced, from ten until four o'clock, on Monday, Wednesday, and Friday in each week; and to scientific foreigners daily. The conservator attends to supply, as far as possible, the deficiencies of the Catalogue.

LIBRARY.

It has ever been the conviction of the Council, that the splendid Collection of Mr. Hunter was limited in its useful application to surgery without the addition of a library, which should be so extensive as to comprehend all the objects for the promotion of which the Collection was formed,—the science as well as the art of surgery. It was not, however, until the year 1827, that the Council considered the time to have arrived when they would be justified in devoting a liberal sum to its formation, and an ample annual outlay for its increase. A commencement indeed had been previously made; one of the members of the Council, the late Sir Charles Blicke,

having bequeathed the sum of £300 in trust for this purpose.

Since the year 1827, the gross sum of £10,172 has been expended in promoting this important object, which the Council believes to have met with general approbation, and to have been found eminently useful as a means of study to the younger, and of reference to the older members of the profession.

The Library comprises a splendid collection of standard and valuable books, as well as of periodical publications in all branches of medical literature and of the sciences connected therewith. It contains nearly 16,000 volumes, and is continually receiving additions of new publications, and of ancient works. It is as accessible to the members of the college, and to the public, as is compatible with due regulations for its security and preservation, with the advantage of a librarian, who is constantly in attendance, and whose services are rendered more valuable by his intimate acquaintance with general medical literature and with the languages in which most of the interesting works appear.

From the extent and rapid increase of the Library, the want of a sufficient space for its arrangement is as severely felt in this department as in that of the Museum.

The Library is open every day from 10 to 4 o'clock, from the 1st of October to the 1st of April; and from 10 to 5 o'clock, during the remaining portion of the year, for all members of the College and their articulated students; except on Saturdays, when it is shut at 1 o'clock, and except also during the month of August, when it is closed for the purpose of revision. In this and in other points the regulations of the British Museum have been as nearly as possible followed.

FINANCES.

The receipts of the College are, and ever have been, chiefly derived from the sum paid for the Diploma*; and inasmuch as there is no well-defined law obliging a student to seek this distinction previously to his commencing practice as a surgeon, the income from this source is uncertain. The expenses of the College and Library, and especially those entailed by the possession of the Hunterian Collection, have been very considerable. It has therefore been a great object with the Council to

* From the period of incorporation up to March 1821, a subscription of one pound per annum was paid towards the current expenses of the College by each member resident in and around London, and two pounds by each member of the council. But as soon as the income and capital justified the remission of these yearly payments, they were discontinued.

realise such a permanent income as may be sufficient to meet this unavoidable expenditure, in the event of their usual annual resources being materially diminished.

The average receipts of the College for the last three years have amounted to, *per annum* . . . £11,116 10 3

The average annual expenditure for the same period has been . . . £8340 18 10

It has been distributed as follows :—

1st. College Department*, including Council, Court of Examiners, Auditors, diploma stamps, taxes, salaries and wages, &c.	£	s.	d.
	4750	17	9
2nd. Museum Department, including the purchase of specimens, spirit, bottles, catalogues, printing, engraving, stationery, taxes, salaries and wages, &c.	1937	10	11
3rd. Library Department, including the purchase and binding of books, book-cases, catalogue, stationery, salary, &c.	934	14	0
4th. Miscellaneous Expenses, including repairs, furniture, law expenses, and incidental payments, &c.	590	15	0
5th. Expenditure under Deeds of Trust, including lectures, Hunterian oration, and Jacksonian prize	187	1	2
	8340	18	10

The present funded property of the College is as follows :—

3 per cent. Consols	£40,000
3 per cent. Reduced	23,000
	—63,000 0 0

* In explanation of this total, it is right to mention, that, upon an average of the last three years, the Court of Examiners meet forty-five times in the year, that each meeting occupied at least six hours; each examiner receives half-a-guinea for every examination for the diploma, and one guinea for his attendance, provided he be present from the commencement to the termination of the court, but no fee for the examination of surgeons and assistant surgeons for the army, navy, and East India Company's service. In addition to the quarterly meetings of the council, their extraordinary meetings, averaged for the last three years, amounted to twelve in each year, that each meeting occupied from two to three hours, and that each member present during the whole of the proceedings, received one guinea for his attendance. But for the numerous meetings of the several boards and committees, occupying much valuable time of the members, no remuneration is received.

The Trust Funds amount to	
3 per cent. Consols . . .	3,307 0 0
	66,307 0 0

It thus appears that the permanent and certain income of the College does not amount to the sum required to meet the annual expenses of the museum alone; and as much additional space is required for the proper arrangement and display of the respective contents of the museum and library, while other parts of the building need extensive repairs, a considerable inroad must of necessity be made at a very early period on the capital of the College, reducing still further its permanent income.

(By Order of Council,)

EDMUND BELFOUR, *Secretary.*

THE CHOLERA CONTINUATION BILL.

OUR readers must be amazed at the consummate wisdom of the Legislature in passing a law for the continuation or diffusion of cholera. Though Parliament is almost omnipotent in its own opinion, we are happy to state that the cholera has set it at defiance, and has taken leave of this country during the last week.

The Legislature must have been guided in this noble attempt to stop the retreat of the enemy by our sagacious friends of Whitehall Place, whose "occupation" is "gone." Perhaps the next step of our Government would be in imitation of that wise monarch, the King of Prussia, who, a few years since, sent three thousand of his brave troops to stop the progress of the plague. We sympathise with the contagionists for the unfortunate non-arrival of their millenium. We congratulate a contemporary on his incontrovertible conclu-

sion as to the contagiousness of cholera. Unfortunately, however, for his argument, this dreadful contagious malady has been destroyed by the equinoctial gales; and he, with his friends, may mourn the hopes that leave them.

The cholera, like all former epidemics, has defied human intervention—has suddenly appeared and disappeared.

It will form a curious statement for the pages of future historians, that in 1832 there was an act passed for the suppression, and in 1833 another for the continuation, of epidemic cholera!

COLLEGE OF SURGEONS.

WE have received a statement from the Council of the College of Surgeons, which will be found in another page, relative to the present state of its different departments. On some future occasion we may examine this document at greater length than the late period of the week at which we have received it will allow of in this number. The present state of the Museum, Library, and Finance Department, are dwelt upon with a complacent spirit of self-satisfaction, which their individual importance (!) would scarcely appear to warrant. Yet are we thankful for the Resolution of the 29th of January—it indicates, we hope, that a better feeling is abroad, and that the Council are willing, as far as in them lies, to do away with that spirit of exclusiveness which has too long formed part and parcel of every one of their acts and deeds.

THE ANATOMY BILL.

WE have the best authority for stating that the Anatomical Bill has not worked its wonders in quite so satisfactory a way to all parties concerned as some of its most sanguine supporters and friends could have wished. The appointment of Inspector gave dissatisfaction to many; nor has the situation been free in its working from all charge of partiality. We know one anatomical lecturer whose prospects and class have been most seriously injured by this system. We trust, however, that the ensuing session will be free from all charge of a like nature, and that no more favour will be shown on the one side than on the other.

TARTARISED ANTIMONY IN SPASMODIC AFFECTIONS.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—In your journal of June 1st, appeared a letter from my friend, Mr. E. Duncan, of Leadenhall street, on the power of tartarised antimony in spasmodic affections, with a case in which it proved beneficial. From repeated trials, I am convinced of its great efficacy. One recent case struck me forcibly when I read the communication alluded to.

Some short time since I was called to a female, ætat. 35, and of a thin spare habit. I found her labouring under violent spasmodic fits, particularly affecting the respiratory muscles, and threatening instant suffocation; the spasm would cease for a minute or two, and then recur as strongly as before. When she felt it approaching, she would express her conviction that it must be the last, and she must die in it. I immediately began, and for four hours administered the most

powerful antispasmodics without any effect. Being somewhat loth to have recourse to venesection or the tartar emetic, in one so apparently debilitated, and without any previous history of the case, I continued the remedies two hours longer without the slightest remission of the symptoms. I was then induced to take twelve ounces of blood from the arm, and used the stimulants for an hour more, but not the slightest amendment took place; two grains of tartarised antimony, with ten of powdered ipecacuanha, were then given in a little water, vomiting ensued almost immediately, a complete prostration of muscular power was the consequence; the pulse became exceedingly small; the skin was covered with a cold, clammy perspiration; the spasms ceased instantly; and the patient exhausted fell into a sound sleep. When she awoke, she felt weak and low, but was perfectly easy, and had no return of spasm. Ordered a gentle aperient.

The following morning I found that she had for four or five years been subject to repeated attacks of a similar nature to the above, at intervals of little more than a month, which usually continued more or less violently, sometimes for eighteen hours, and seldom less than ten. She had been to many medical practitioners, and taken much medicine, and had passed a portion of tape worm about nine months before. Complains of constant desire to eat, with a gnawing pain at the scrobiculus cordis, and loathing at the sight of food. Suspecting tænia to be the cause of all her suffering, she took three strong doses of the sp. terebinth. at an interval of two days between each dose, followed by a draught of castor oil; this brought away no worm, but a very large quantity of slimy, offensive matter. She went into the country, where she has remained three months, has had no one symptom of her old complaint, and has now returned, to use her own words, "quite hearty." I think it right to state my belief,

that a large dose of the tartar emetic administered to a weak, debilitated subject, might produce fatal syncope, and it is not, therefore, a remedy to be used in trifling cases.

I am, Gentlemen,

Yours, &c.

JOHN C. W. DYER.

Chapel-street, Pentonville.

Aug. 28th, 1833.

French Medicine.

Cases of Hooping Cough treated by Tartarised Antimony.

Case 1.—Jean Pierre Lamblia, aged five months and a half, was attacked with catarrhal cough, which soon degenerated into hooping cough, with twelve or fifteen paroxysms in the twenty four hours, and but little fever. An emetic composed of ipecacuanha and squill seemed to moderate the cough somewhat, but it soon returned with increased vigour. There were slight convulsions, and incipient hydrocephalus was feared. An ointment composed of ʒiiss. of tartarised antimony to ʒj. of lard was ordered. The third day there was a slight pustular eruption on the base of the thorax, and the hydrocephalic symptoms were diminished. On the fourth day the pustular eruption had increased, and the paroxysms of coughing, without being lessened in violence, had decreased to seven in the twenty-four hours. On the following day they were only three in the twenty-four hours. The ointment was ordered to be used in smaller quantity; but the parents, willing to spare the infant the pain, neglected it altogether, and the cough returned with increased violence every quarter of an hour. An emetic was administered, and the ointment used four times in the day. In four days the cough had degenerated into a common catarrh, and in another fortnight was quite well.

Case 2.—Jaques Brader, aged three years, had hooping cough for ten days.

The paroxysms occurred eight or ten times in the twenty-four hours. The tartarised frictions were commenced. On the following day, a slight pustular eruption was visible on the lower part of the chest; no abatement of the cough. On the fourth day the pustular eruption was more marked, and the expectoration was easy and abundant in quantity. The antimony was used for the two following days, and in the course of a week the cure was complete.

Case 3.—Lisette Ham, aged three years, had been affected with whooping cough for three weeks. The paroxysms, which were violent and frequent, were succeeded by vomitings. The whooping cough was preceded by measles. Four days after the use of the ointment there was a free crop of pustules; the cough gradually diminished, and in the course of a week had degenerated into a common cough; one or two large pustules had become ulcerated, but soon healed. In the course of a week the cough entirely ceased. This patient had two brothers who were cured in a very short time by the same means.

Case 4.—George Adam, aged six years, of strong constitution, had been affected with whooping cough for 20 days; the paroxysms accompanied by vomiting returned twelve or fifteen times daily. There was slight fever and irritation of the stomach. He was ordered the ointment, which soon brought out a pustular eruption over the base of the thorax and epigastrium; while at the same time the right half of the scrotum, and that part of the thigh in contact with it, had also a slight pustular eruption over them. These caused the little patient some pain, but they soon encrusted over and disappeared. At the end of sixteen days he was quite well.

Case 5.—J. Jung, aged 25, was affected with nervous irritation of the stomach, accompanied with oppression at the chest; it had lasted three

weeks, and he could assign no reasonable cause for it. The accessions came on at irregular intervals, and lasted sometimes for several days, accompanied with great pain over the epigastrium, which was slightly relieved by pressure; anxiety, want of appetite, but no fever. An ointment (3iss. of antimony to ʒj. of lard), was ordered to be rubbed three times a day over the epigastrium and base of the thorax. On the third day there was a plentiful pustular eruption, which soon affected the scrotum. The frictions were discontinued for a short time; the eruption over the scrotum passed away; that on the chest remained, where one pustule degenerated into an ulcer, discharging freely, which was of great benefit to him; and in a short time he was free from all disease.—*Ibid.*

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Rupture of the Urethra and Laceration of the Perineum from violence.—A young lad of thirteen years of age, came into the hospital some days ago, with a ruptured urethra. While playing with his school-fellows some days previously, he fell with great violence on an iron bar, which extensively lacerated the perineum, and ruptured the corpus spongiosum of the urethra. The urine has been since voided through the ruptured aperture. On Saturday, Aug. 24, in consequence of some clots of blood becoming solid and stepping up the opening, the urine could not be passed through it; nor on the patient's attempting to evacuate the bladder through the natural passage could he attain that object. Mr. Stanley accordingly passed the catheter, and about a quart and a half of urine was removed. The testes are considerably inflamed and enlarged, having received some injury in the accident.

Fungus of the Testicle.—There is a case of fungus of the testicle at

present under Mr. Vincent's care, which came on spontaneously. It commenced with an enlargement in the body of the testicle. The constitutional health of the patient has not been much impaired. The iliac glands are somewhat enlarged above Poupart's ligament. On feeling it, it is hard and firm, about the size of a small orange. The epididymis is also affected. The testicle has been leeched several times without any good effects, he is now ordered to take,

Tinct. Iod., ℥ x. ter in die.

Extensive Syphilitic Ulceration.—

There is a very strongly marked case of syphilitic ulceration at present in this hospital. The patient is a female of sanguineous temperament, æt. 40. Large ulcerated blotches are scattered universally over her body, and particularly on her face. By her own statement she was perfectly sound three years ago, and denies that sores ever existed on the pudenda. She however acknowledges that there was a discharge from the urinary passage. Mr. Stanley said that there might have been a sore there without her knowledge. Ordered her to have generous diet and prescribed,

Ext. Sarsaparillæ ʒss. ter in die.

Mr. S. added that he had no doubt whatever of being able to dry up the ulcers by this treatment.

Erysipelas of the Head and Face.

—In a case of erysipelas of the head and face Mr. Stanley ordered cold spirituous applications to the head; and, when the pulse indicated it, bleeding from the arm.

Ventral Hernia.—A robust man, æt. 42, came into the hospital the other day under Mr. Vincent's care, complaining of great shortness of breath and considerable pain in the abdomen on coughing. On examination, we found a small oval tumour situated on the surface of the abdomen, a few inches above the umbilicus, and between the recti muscles. There was a decided impulse given to the tumour

when the patient coughed. His general health is very much impaired, and he is deprived of sleep by the pain which every fit of coughing induces. Mr. Stanley, on seeing this case, said that the ventral hernia was the result of a deficiency of strength in the structure of the linea alba, in which it was not uncommon to find small openings, through which portions of fat and afterwards intestine protruded. The application of a truss will be sufficient for his cure.

ST. GEORGE'S HOSPITAL.

Ligature of the Femoral Artery for secondary Hæmorrhage after amputation.—In one of the cases of amputation of the leg (disease of the knee-joint) which we noticed in our last week's report, secondary hæmorrhage has ensued. The hæmorrhage commenced on the eighth day after the operation, and a considerable quantity of blood was lost by the patient. By the application of ice, &c. the hæmorrhage was for a time arrested, but recurred with great violence last Monday night. Mr. Keate was sent for, but some circumstances having occurred to prevent his attendance, Mr. Hawkins in his absence, in order to save the patient's life, cut down on the femoral artery, and after the usual incisions passed a ligature round it. The incisions were made within a short distance of Poupart's ligament. Since the operation the patient has gone on well. His strength however has been considerably lowered by this unforeseen occurrence.

Concussion of the Brain.—Mr. Keate on coming to a bed where there was a case of concussion of the brain, seemed highly displeased at finding the patient sitting with his clothes on reading a book, and desired him to strip off and go to bed immediately, and not to read any books for some time to come. Mr. Keate remarked, that in cases of concussion of the brain, the patient should be always prevented from reading for a long

time after the accident; he should also be kept in a dark room.

Hæmorrhage from the Gums.—

There is an out-patient at present on Mr. Hawkins's books who has been troubled with hæmorrhage from the gums for several months. She was affected with fever some time ago, and on her recovery the bleeding from the gums commenced. Alum water, &c. have been used as astringents. The hæmorrhage though it has not entirely ceased, has become less frequent and copious by the astringent application.

Enlarged Mammary Glands.—

There is also a case in Mr. Hawkins's out-patient book of enlarged mammary glands. The patient is a stout-looking woman about forty; the size of the breast is unnaturally enlarged, and she complains of the pain in her throat on coughing; this proves the bronchial glands also to be enlarged. Iodine has been exhibited to diminish the enlargement of the glands.

Tumour on the Cheek.—A man came to Mr. Walker the other day with a small hard tumour on his cheek, which he wishes to have extirpated. On its being examined it felt very hard and firm; it is situated on the lower part of the right cheek, midway between the mouth and ear. It first made its appearance in the form of a very small pimple, about the size of the head of a pin. It is now about the size of a nut, and does not inconvenience the patient in the least; he is however anxious to have it removed, as he considers it a deformity. It has increased in dimensions during the last few days. Mr. Walker will extirpate it next Monday. Mr. W. thinks it may have something to do with the duct.

Hare Lip—Operation.—A child was brought to Mr. Keate the other day with hare lip, it was only a fortnight old, and could not suck properly. The fissure extended from

the edge of the lip nearly to the nose. Mr. Keate proposed operation, to which the woman who had the care of the child at once consented. Having placed the child recumbent with his head over a pillow, Mr. Keate extended the incision from the nose, and having introduced a curved bistoury at the angle of the fissure, he brought it down to the red part of the lip, and in this manner removed the surface from each side. A needle armed with silk was then drawn through each side of the lip at that part where the skin joins the red part of the lip, then another needle was introduced through the integuments midway between the first suture and the angle of the fissure. The edges of the fissure were approximated by tying the silk threads. No adhesive plaster was applied, as in such cases it is better that the part should be exposed to the air as much as possible. There was some hæmorrhage from the superior coronary artery, but not such as to require a ligature.

Four days after the operation the sutures were removed; first the upper thread was drawn away, and on the next day the inferior one was also removed. The child can now suck very well, and a complete union has taken place between the divided parts.

Compression of the Brain.—John Walkins was brought into the hospital on the 26th August, having fallen from a height of several feet. On his admission his pulse was hardly perceptible; the pupil was considerably dilated; breathing stertorous and difficult. He fell into convulsive fits three times during the night; and vomited an immense quantity of blood. All the symptoms of concussion were present. When Mr. Hawkins saw the patient on Tuesday, he said that though he could not discover a fractured rib, he believed there was rupture of the lung, which accounted for the vomiting of the blood. The convulsions fits were caused by pressure of blood on the brain, and were to be

considered as bad symptoms. There was great nervous irritability in this case, and the patient could not bear the least touch without complaint. When Mr. Hicks (the house surgeon) was dressing his head, he vociferated most loudly, and spoke in a rambling incoherent strain. Mr. Hawkins ordered him to be bled, should the pulse rise. Purgatives were administered.

Concussion of the Brain.—Two working bricklayers were conveyed into the hospital on Tuesday morning, Aug. 27th. They had been working on a scaffold which suddenly giving way they were precipitated from a height of fifty feet. The fall of one of the sufferers was broken by his coming on a board, but the other fell with violence on the pavement. In the latter case the patient was insensible for many hours after admission; respiration slow and difficult. He lay in a tranquil sleep during the entire day of the accident, pulse beating steadily and with its usual velocity. The carotid arteries beat violently. Purgatives were given immediately on his admission. Mr. Hawkins requested Mr. Hicks to bleed him, after which the patient improved. Mr. Hawkins urged on the pupils the necessity of knowing well the state of the pulse before bleeding should be ordered. Bleeding should be used with great caution in cases of concussion, and should be resorted to as a means of avoiding inflammation, and not as a matter of course. A day or two after the accident will often be time enough in such cases, "but above all," said Mr. H., "let the pulse be your guiding star." In the evening Mr. Hicks took a large quantity of blood away from the patient's arm.

GUY'S HOSPITAL.

Exostosis of the Scapula.—A lad, æt. 12, was admitted into the hospital a few days ago with a very large

exostosis, extending along the entire spine of the scapula. It is firmly attached to the scapula, and is as hard as ivory. It does not give the patient much pain, but seems to have considerable influence over his general health, which is much impaired. The lad is of a scrofulous habit, and has an anxious look. There is no other exostosis on his body. The exostosis on the scapula is unusually large. Sir Astley Cooper has seen the case, and recommends its immediate removal: he also advises the removal of the periosteum of the scapula.

SIR PATRICK DUN'S HOSPITAL. (DUBLIN.)

Mortification of the Liver.

MICHAEL BRYAN, aged 50, was admitted on the 4th of March. He states that he is temperate in his habits, and had been healthy until about six months ago, when having eaten a very hearty dinner, chiefly of vegetables, he was suddenly seized with violent pain in the stomach and right hypochondrium, which lasted for twenty-four hours and then subsided, leaving him, however, ever since, subject to pains in the side, cramp, and wind in the stomach, with some swelling in the abdomen, which last partially yielded to purgatives. On examination, the liver was found very much enlarged, and protruding far beyond its natural limits, so as to be distinctly felt, forming an extensive tumour in the right and left hypochondrium and epigastrium, which was hard and painful when pressed. The patient was jaundiced, and his stools destitute of bile, were loose and frothy, resembling barm; the urine was deeply tinged with yellow; he could not lie on his left side; had no pain in either shoulder; said that his present attack commenced about three weeks ago, at which time the pain and swelling of the liver were observed, and were followed by œdema of the feet and legs and ascites. His pulse is frequent, small, hard, and regular; tongue very foul; all appetite extin-

guished; and he complains of great debility.

It was evident that the patient's disease was of long standing; and I concluded that his liver must have been enlarged long before the period he assigned as the commencement of his illness. The combination of enlargement of the liver, evidently of long standing, with dropsy, emaciation, and jaundice, in a man of his age, I at once pronounced fatal. While in the hospital his sufferings were much increased by tympanitic distension of the bowels; and from the day of his admission until his death, which took place on the 15th of March, he continued rapidly to grow weaker. No rigors or other symptoms indicative of any peculiar termination of the hepatic inflammation occurred until six o'clock in the evening of the 14th, when, after having all the day complained of excessive abdominal pain and tenderness, and being evidently sinking, he suddenly began to vomit an extremely foetid fluid, mixed with a dark grey substance. This vomiting returned at intervals until five o'clock on the following morning, when he died, without suffering much pain immediately previous to his death.

Autopsy twelve hours after death.

—On opening the abdomen, about one gallon of serous fluid, deeply tinged with bile, flowed out; the liver was greatly enlarged, extending below the umbilicus, and part of its surface was covered with recently effused lymph. Large white solid formations, resembling cartilage, studded its surface, and were found in its interior. They were cupped or concave on their surface, and homogenous, and consistent in their texture. By some they have been denominated *large white tubercles*, by others, their nature has been compared to *scirrhus*. Between them the texture was everywhere healthy. In the inferior portion of the left lobe there was an excavation larger than a man's fist, and half filled with a dark grey slough of an extremely offensive smell, and precisely similar to the substance he

had vomited. This slough was very dry, its fluid having probably been drained off by the large opening which formed a communication between the excavation in the liver and the stomach. The sloughy appearance extended to that part of the pancreas which lay in contact with the stomach, and another perforation of the latter had been formed in its place. An evident line of demarcation existed all round the hepatic excavation, closely resembling in breadth and appearance that which announces, in external parts, that nature has succeeded in arresting the progress of the disease, and is preparing for the separation of the dead from the living structure*.

* The above case, which we extract, is from the practice of Dr. GRAVES, recorded in the *Dublin Medical Journal*, and forms a very rare termination of hepatitis. Neither Andral, Morgagni, or Mason Good speaks of it. Richter observes, that in no organ is gangrene so rare as in the liver. Frank says, that its occurrence "may be conjectured from the presence of symptoms indicative of gangrene in general;" and Dr. Mackintosh remarks, that he believes gangrene to be unknown as a termination of hepatitis.—Eds.

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LIV., DELIVERED FEB. 18, 1833.

GENTLEMEN,—We now enter upon the consideration of the *diseases of the blood-vessels*. The diseases of arteries and veins may be said to constitute one of the most interesting departments of surgery. In the lectures, already delivered on the mechanical injuries of arteries, I partly introduced you to this subject, the greater portion of which still remains to be explained. In the account of the mechanical injuries of arteries, I reminded you, that these vessels are furnished with arteries, veins, lymphatics, and nerves, of their own. It would, therefore, be superfluous to detain you again on this topic, on which I have no doubt you will receive the most correct information from the Professor of Anatomy. As the arteries partake of this general organisation of other textures, you will of course see, that they must be liable to many of the ordinary forms of disease, to which other parts are subject; and especially, that they must be liable to inflammation, ulceration, suppuration, and sloughing. They are also subject to the deposition of calcareous matter between their internal and middle coats, and to several other deviations from the natural and healthy state: particularly, to a steatomatous thickening of their coats, to a dilatation of them, to an obliteration of their canal, and to various other affections, which will presently be noticed.

The internal coat of the arteries is more subject to inflammation than the external and middle ones. This is proved by the frequency of effusions of lymph on the inner coat, in consequence of inflammation of the neighbouring parts; and the same effect follows the application of a ligature, or any accidental irritation in the neighbourhood of the vessels, like that

resulting from the pressure of a tumour. Sometimes the inflammation, thus excited, will extend to a considerable distance along the canal of the artery—in some instances, even as far as the heart itself; and when the affection thus spreads to any great extent, the name of *arteritis* is usually given to it. *Chronic inflammation* of the arteries is frequently met with, as a consequence of the deposition of calcareous matter between their internal and middle coats. However, gentlemen, I would not always have you to conclude, that an artery has been inflamed, merely because the internal tunic may have a red appearance in the dead subject: this criterion is frequently a deceitful one; at all events, remember, that after exposure to the air, and the commencement of putrefaction, the inner coat of the arteries commonly presents a red tinge; and you should be careful not to confound this condition with the appearance presented by real inflammation.

Although the larger arteries are capable of resisting *ulceration* for a long time, they are occasionally attacked by it. While an artery is healthy, and under circumstances not unfavourable to its nutrition, it is capable of resisting the destructive effects of ulceration for a very long period. But when the external coat has been separated for some distance from its surrounding connexions, the vessel is then liable to ulcerate, and even to slough; and I may make the same observation respecting an artery in a diseased state. You will find arteries, not only pervading the generality of diseased structures, without becoming ulcerated, but absolutely situated in the midst of the worst fungoid, tubercular, and cancerous diseases, defying, as it were, for a surprising length of time, the ravages of those complaints. This disposition of the arteries to resist ulceration is strikingly illustrated by what occurs in the extensive abscesses often found in the lungs in tubercular phthisis. Here you will find bands, or filaments, extending across the chasm, which are, in reality, blood-vessels that have as yet escaped destruction. According to the investigations of Professor Andral, it would appear that blood-vessels sometimes extend, in the form of filaments, across abs-

cesses in other situations; so that if an instrument be introduced into the collection of pus, through which such filaments extend, hæmorrhage is occasioned by the laceration of them. These fræna are thus regarded by Andral, as consisting chiefly of blood-vessels which have escaped the destructive ravages of the ulceration going on around them. Sometimes, however, arteries, surrounded by disease, at length ulcerate, of which we have frequent examples in cancer, phagedænic ulceration, and gangrene, and the dreadful disease termed *hospital gangrene*, which is, in fact, a kind of phagedæna.

The internal coat of an artery may ulcerate primarily. Andral mentions instances in which he has seen ulceration in this form, sometimes only at one point of the whole arterial system, sometimes at many points. Occasionally he has seen the aorta studded with small ulcers of this description.

Arteries are liable to *suppuration*. In one case Andral found, under the lining of the aorta, no less than eight abscesses, each of which was as large as a nut. Pus is also sometimes met with in the cavity of the arteries, a fact which I noticed to you in a former lecture. All the branches of the pulmonary artery have been seen in this condition, viz., filled with purulent matter. Pus is not found between the internal and middle coats of the arteries, so often as another matter which is peculiar to that situation, and which has been called an *atheromatous* or *pultaceous substance*, with which you will generally find blended a gritty matter like sand: sometimes, indeed, the composition is more like mortar or plaster, than osseous matter. These calcareous depositions are more common in elderly persons than in young ones: in fact, they are so common in old persons, that, according to some calculations, after the age of sixty, the arteries of seven-tenths of the human race are thus affected. This estimate, which was made by Bichat, coincides with the observation of Dr. Baillie, who remarks, that after the age of sixty, the number of individuals, having arteries thus diseased, far exceeds the number of those who are entirely free from a similar affection. However, gentlemen, I do not wish you to imagine, that young persons are wholly exempt from these calcareous concretions; ossification of the temporal artery has been noticed in children under the age of fifteen months, and Mr. Wilson met with an ossification of the aorta in a child aged only three years. You are not to conclude, therefore, that this disease is confined to old persons. In a girl aged eight years, and in four or five others, whose ages were between eighteen and twenty-four, the aorta was studded with calcareous deposits; and in another under forty years of age, there was an ossification of the superior mesenteric artery.

Strictly speaking, the internal coat of the artery is not the seat of the calcareous formations now under consideration: as I have

already mentioned to you, they are produced between the internal and middle coats. Under these circumstances, the inner coat is often partially absorbed, so as to allow the calcareous matter actually to project within the cavity of the artery. This is illustrated in the preparation which I am now going to send round to you, and in which you will observe an immense number of calcareous patches, portions of which project into the cavity of the vessel, the aorta. The next preparation before us is the carotid of a horse, in which you may notice the same appearances. Cases do sometimes occur in which the inner coat itself is ossified, converting the artery into a true bony rigid tube; but that kind of change should not be confounded with the more ordinary form of disease, consisting of the deposit of calcareous matter between the inner and middle coats of the vessel. While these deposits are forming, the middle or fibrous coat undergoes some changes; sometimes it is wasted or absorbed, in other instances it is thickened; when it is absorbed, its place is occupied by the calcareous matter. An analysis of these calcareous formations, found between the internal and middle coats of arteries, proves them to consist of phosphate of lime and animal matter, in the proportion of 65 parts of phosphate of lime to 35 parts of animal matter in every 100.

These calcareous deposits are formed nowhere more frequently than in the aorta, and they have been met with in all its branches. However, some difference prevails in this respect in the abdominal branches; for, while the splenic artery is frequently ossified, the hepatic and the coronary artery of the stomach are rarely the seat of calcareous formations. The arteries of the limbs are well known to be frequently made rigid by calcareous matter, and there are few surgeons of experience who, in feeling the pulse, have not had many opportunities of perceiving, that the radial artery is liable to this change in the living subject. In the preparation which I now pass round, you have an example, in which the common iliac artery has between its proper coats a complete stratum of earthy matter; you may observe plainly, that there are calcareous deposits under the inner coat, which is peeling off. The next preparation is a portion of the popliteal artery, in which the same morbid changes are exhibited. The latter preparation proves, then, joined with what we know respecting the radial, temporal, femoral arteries, the arteries of the brain, and other vessels, that the disease is not confined either to the thoracic aorta or to the arteries of the abdomen.

But I ought to mention, gentlemen, that the arteries of the upper extremities are more rarely ossified than those of the thigh and leg. You will frequently meet with calcareous deposits between the inner and middle coats of the femoral and popliteal arteries, but very rarely between those of the brachial, ulnar,

and radial arteries. Sometimes you will find an artery completely encrusted with calcareous matter, so as to be converted into a rigid inflexible tube. Occasionally, the phosphate of lime is blended with the atheromatous or pulsatous matter, to which I have already alluded: and, then, it becomes the foundation of *aneurism*, a disease, with the nature and varieties of which all practical surgeons ought to be minutely acquainted.

This preparation, gentlemen, is a portion of the aorta, in which may be observed the commencement of an aneurism, following the secretion of calcareous matter under the internal tunic; it furnishes a good illustration of the disposition, which that peculiar change of an artery creates to aneurismal disease. You may remark, that, in this example, the aneurism is just above the semilunar valves of the aorta, the whole of which is studded with calcareous deposit.

There is one circumstance deserving of your attention, gentlemen, with respect to the pulmonary artery, and the aorta and its branches; the pulmonary artery is very rarely the seat of disease; the branches of the pulmonary artery do not anastomose and communicate together, but continue separate to their very termination; and notwithstanding the coats of the pulmonary artery are very similar in structure to those of the aorta, the former of these vessels is seldom the seat of any morbid changes. But the aorta is frequently the place of disease, and the same may be said of all its branches: we know also that they anastomose freely with one another every where throughout the body. The observations which I have delivered will at once inform you, that the pulmonary artery is far less interesting to the practical surgeon, than the aortic system of arteries.

Let us next, gentlemen, direct our attention to the subject of *aneurism*, the study of which will fully reward your industry, by convincing you of the inestimable value of surgery, as a means of relieving the most formidable diseases.

An *aneurism* may be defined to be a tumour arising from the rupture, wound, ulceration, or simple dilatation of an artery; for you may have a tumour containing blood, produced by any of these circumstances. An aneurism is generally represented to be a pulsating tumour; but this description does not appear to me correct, for, in particular stages of the disease, there may be no pulsation at all. The tumour is filled with blood, which is sometimes fluid, and sometimes to a greater or less extent solid. When an aneurism is recent, the blood is in a fluid state; but after some time, the portion of blood nearest to the interior of the aneurismal cavity is deposited in a concrete form, and arranged in concentric layers. Sometimes the aneurism arises from an alteration of structure, and consequent dilatation of all the coats of the artery; in other instances from the dilatation of the external coat alone,

the two internal ones having given way. As long as the sac, formed by the coats of the artery, is complete, the disease is termed a *true aneurism*, and this term might, perhaps, with propriety be applied also to examples, in which the internal and middle coats have given way, while the external one is simply dilated and not ruptured. When the coats of the artery have given way, or have been wounded or lacerated, then the case usually receives the name of a *false aneurism*. In this instance the blood may be injected to some extent in the cellular membrane; or if there be a wound, a part of the blood may escape externally, and on the external orifice healing, another portion of the blood may either be diffused in the cellular membrane, or accumulate near the aperture in the vessel in one mass. The two first mentioned cases would both constitute what is called a *diffused false aneurism*; and the last a *circumscribed false aneurism*. One particular form of aneurism is very rare, and, indeed, the reality of it has been doubted, namely, the case in which only the external coat of the artery gives way, and the internal and middle coats protrude, almost in the manner of an hernia, through the external one. I have stated, that the reality of this modification of aneurism has been disputed; but certain preparations, in the possession of Baron Dupuytren and Dr. Breschet at Paris, completely establish the fact, that such a form of disease may occur. However, gentlemen, you are to understand, that these preparations only demonstrate the possibility of this variety of aneurism, as far as regards the aorta, the lining of which is well known to be more elastic than that of any other artery, and is truly capable of protruding through the external and middle coats when a portion of these happens to be destroyed. The reality of the kind of aneurism, of which I have just now been speaking, was at one period denied, chiefly in consequence of the experiments of Hunter, Scarpa, and Sir Everard Home, who purposely dissected off the external and middle coats of the arteries, in order to see whether the removal of the support of those tunics would lead to the protrusion of the internal coat, in the form of an aneurismal sac. Now, they found that no such event followed, and hence they inferred, that the variety of aneurism alluded to, was only an imaginary disease. However, as I have said, as far as the aorta is concerned, its reality has now been sufficiently proved by careful dissections, the preparations from which are preserved in the museum of the Ecole de Médecine at Paris.

Besides the preceding varieties of aneurism, there is another, which is improperly called the *venous or varicose aneurism*, consisting of the dilatation of a vein, produced by the gush of blood into it from a neighbouring artery. Of course this implies a preternatural communication between the two vessels. As for the *aneurism by anastomosis*, as it is

called, it ought not to be classed with aneurisms, for there is no resemblance or analogy whatever between such a disease and what we understand by an aneurism. The former is, in fact, a new formation, the growth of a peculiar texture in the body, which is compared by French pathologists to the *erectile tissues*, and consists of a spongy vascular substance, that has an extraordinary tendency to bleed, so that the slightest wound or breach in it is frequently followed by an alarming and even fatal hæmorrhage. This species of tumour, I think, is more judiciously arranged with *navi*, and, with this class of diseases I propose to consider it in this course of lectures.

The truth of the doctrine, that aneurisms may be formed by the dilatation of all the coats of the artery, unattended by the laceration of the two internal ones, or, in other terms, the correctness of the doctrine of true aneurism, was denied by Professor Scarpa, who considered that, in every instance of aneurism, there was either a wound, a laceration, or an ulceration of the internal and middle tunics. However, the best modern pathologists, deducing their knowledge from a wider field of observation than Scarpa happened to enjoy, pronounce the old doctrine to be correct, which maintains, that diseases of the arteries are met with, corresponding in every respect to *true aneurisms*, or those which consist of a dilatation of all the coats. Experience proves, that such dilatation sometimes presents itself in the early stages of aneurism, though in general the internal and middle coats afterwards give way. My friend, Mr. Hodgson, of Birmingham, has completely proved this fact by dissections of cases in his own practice. Here is a drawing, made from one of his preparations, and you may observe, that all the coats of the artery are implicated in the dilatation, and extend to every point of it. Another figure in the same plate is a portion of the popliteal artery in the state of aneurism, where the three tunics are distinctly seen contributing to form the aneurismal sac at every part of it. Then, in the next engraving, you see a delineation of an aneurism of the aorta, where the three coats of that vessel were traced to a certain distance on the tumour, where they were found to terminate. The rest of the sac was formed by the lungs; for it is the nature of aneurisms in general ultimately to make their way through all the coats of an artery, and then the contents of the tumour become bounded by the sheath of the vessel, which itself giving way, in a subsequent stage, brings the contents of the aneurism in contact with any texture that happens to be near the disease, which texture, whether lung, muscle, or any other soft part, or even the naked surface of a bone, then assists in forming the boundary of the aneurism. Here you see a portion of the lungs constitutes a part of such boundary. In the examples, from which these engravings were taken, the three tunics

were plainly and unequivocally dissected, and made out separately on the tumour: the cases, therefore, furnish a demonstration of the truth of the doctrine of true aneurism, or aneurism with dilatation of all the coats of an artery.

Now gentlemen, you will meet with this form of aneurism more frequently in the aorta, than in any other artery; but the possibility of its occurrence is proved by the preparation from which this drawing is taken, exhibiting a portion of the popliteal artery affected with aneurism. Mr. Hodgson has also noticed the same kind of dilatation at the bifurcation of the carotid, and at the commencement of the common iliacs. Notwithstanding the possibility of an aneurism with dilatation of all the arterial coats has been fully demonstrated, yet, gentlemen, in by far the greater number of cases, the changes do take place, which Scarpa insists upon, namely, the internal and middle coats become diseased, as I have explained, in consequence of the interposition of an atheromatous and calcareous secretion between them, ulceration follows, and then the external coat becomes dilated. In the early stage, however, you will sometimes be able to trace all the coats of the artery stretched over every part of the aneurism.

Frequently when the disease consists of dilatation only, without rupture of the internal and middle coats, the swelling is oval; but when those coats have given way, it is globular, and makes a kind of lateral prominence on the vessel. Scarpa considered, that, when the dilatation is such that the whole circumference of the artery is implicated, the disease is not aneurism, but simply *dilatation*; and he makes the following distinction between the two cases; in an aneurism, the blood is deposited in concentric layers of a fibrous substance; but, in simple dilatations, including the whole circumference of the vessel, no laminated blood is deposited, unless the internal and middle coats should give way or become imperfect, and then you will observe that at those points the blood will be deposited in concentric layers, and at no others. Then he remarks, that, in an aneurism, the communication between the cavity of the tumour and the canal of the vessel is narrower than the diameter of the swelling itself, so that the strength of the current of blood within the aneurism is considerably impeded and lessened, and hence the disposition of this fluid to coagulate, in the form of concentric layers is materially promoted; but, in the other form of disease, consisting of simple dilatation, the blood actually flows in its natural course, and its current is not checked, which is the reason of the difference I have mentioned. Whatever you may think of these distinctions, the facts are worth remembering; for they are incontrovertible. Another difference also of some importance between the two forms of disease, is this; the one consisting of a simple dilatation of the whole circumference of the artery, is incurable; whereas the aneurism may be suc-

successfully treated. Scarpa admits, however, that a simple dilatation may become an aneurism, or rather that an aneurism may be grafted on it, on the giving way of the internal and middle coats at some point of the dilated portion of the vessel, examples of which he has given in his work.

Whether the aneurism begin with dilatation, or not, a rupture of the internal and middle coats generally follows after a certain period, and the external one then becomes dilated in the form of a sac, and constitutes the most convex part of the tumour. After a time the external coat itself gives way, and the sheath of the vessel constitutes a part of the boundary of the aneurism, until that also bursts, when the aneurism is supported by whatever texture happens to be external to the sheath: therefore, in an aneurism in the chest, you will frequently find, what I have already explained, a portion of the lungs forming the boundary of the aneurism. In the case from which this plate was taken, the sac at first consisted of all the coats of the artery, which giving way, extension of the aneurism beyond the ruptured or ulcerated opening followed, and a new cavity for the blood was formed in the substance of the lungs. In this instance, the patient ultimately bled to death, the hæmorrhage taking place through the bronchi.

In a few very rare cases, the rupture of the internal and middle coats is not followed by the aneurismal protuberance, or dilatation of the external one; but after the blood has made its way through the internal and middle coats, it travels a great way between the middle and external coats. Laennec met with an instance, in which the blood travelled in this manner down the aorta as far as the common iliac; there was a narrow transverse fissure in the internal and middle coats, through which the blood passed, dissecting, as it were, the middle coat from the external, from the arch of the aorta, even as far down as its bifurcation into the common iliacs. Fissures of this kind are the result of a calcareous deposit. However, these are exceedingly rare cases, and, I believe, only three well-authenticated ones are on record, namely, that observed by Laennec, and two similar ones mentioned by Mr. Guthrie. In the third vol. of the Dublin Hospital Reports; another still more curious case is described by Mr. Shekelton, where the blood, after passing through the internal and middle coats, travelled down between the latter and the external one, and by its pressure actually obliterated the original channel of the vessel, another communication with the continuation of the old canal below the obliteration being produced, so that the original course of the blood was entirely changed. This very singular case is worth remembering, as constituting one of the most extraordinary varieties of aneurism that I have ever heard of. However, I do not expect, that you will ever meet with such a case, and that reported by the late

Mr. Shekelton is the only one, I believe, that has yet been noticed. Gentlemen, I will go on with this subject in the next lecture.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XI.

Diphtheritis—Phthisis Laryngea—Dropsy.

GENTLEMEN,—The first case, to which I shall direct your attention to day, is a remarkable instance of the disease termed *diphtheritis*, occurring in the person of a man named Lynam, who is at present under the care of Mr. Power. The general history of his case is, that he was admitted on the 10th of August, labouring under an attack of double pneumonia; he had, in fact, intense and neglected inflammation in both lungs; and, when he came into hospital, all the symptoms and signs of a violent pulmonary inflammation were present. The patient was, however, of a robust and strong habit, and did not, at the period of his admission, exhibit any appearance of gastro-enteric disease. A short time after he came into the hospital a quantity of blood was taken from his arm, which, on subsequent inspection, was found to be neither buffed nor cupped. Now, this was very remarkable, and interesting in a certain point of view, because, on a second bleeding, the blood presented an extraordinary coat of buff; and, in consequence of this, looking on it as an acute case, I was induced to treat him by bleeding, leeches, and tartar emetic. If he had manifested any symptoms of the typhoid pneumonia, or gastro-enteric inflammation, I would not have acted in this manner, for reasons which I have detailed in a former lecture. Under the treatment employed he experienced decided relief. He continued to use the antimonial solution for three or four days, during which he took eighteen grains of tartar emetic, and bore it remarkably well. On the fifth day a new train of symptoms appeared, and the report is as follows:—"His cough has, within the last few hours, assumed a laryngeal character; his voice is husky, and articulation difficult; his breathing laborious; and he complains of great soreness in his throat." On examination, several thick patches of a dense, firm, white substance were found on the tongue, velum, and back of the pharynx. Here, gentlemen, was a new disease, shown by exudation of this peculiar membrane and laryngeal cough. On the other hand, the original affection had been much alleviated; the right lung was almost healthy; and the left, which had been extensively dull on percussion, had nearly regained its natural

clearness of sound. We immediately omitted the use of the tartar emetic; in the first place, in consequence of the resolution of the pulmonary inflammation, and secondly, on account of the supervention of this new disease. A large blister was applied to the throat, and the exudation on the fauces was brushed freely with a camel's hair pencil dipped in the strongest muriatic acid. On the seventh day, the report is, that he is improving rapidly; the patches of thick mucus are nearly detached; and it has been thought advisable not to apply the acid any more. The next day, however, his voice again became husky, and the laryngeal cough returned; we therefore ordered him to have the decoct. polygalæ, to use the muriatic acid again, and have his bowels freely opened. To-day his voice is clearer and louder, his cough better, his breathing is not so stridulous, and he states that he feels much better.

Gentlemen, this diphtheritis is a most formidable disease, and one which I believe very few of you have witnessed before. It is analogous, in many of its most prominent features, to that affection which the old medical writers called *cynanche maligna*; at all events, it resembles it in this, that in both there is the formation of a dense albuminous pellicle (whence the name); and I think that, as far as it goes, we may call it a species of croup in the cavity of the mouth and pharynx.

I said before that this was a formidable disease, and you will ask, perhaps, in what its danger consists? In the first place, it is characteristic of a bad state of constitution; in the next, we have another source of danger depending on a mechanical cause. What is it that we observe in this affection? This membrane is formed on the tongue, velum, tonsils, and back of the pharynx; if not arrested, it creeps on until it reaches the larynx; the inflammation continues its destructive career; and the patient may die with all the symptoms of croup; in fact, he dies in the same way as a person who has swallowed a quantity of boiling water. When a patient dies soon after swallowing a quantity of boiling water, it is generally not from the amount of injury done to the digestive tube, but from an extension of the inflammation to the larynx; and in this disease the inflammation travels in precisely the same way. Lynam was on the point of losing his life by croup; his laryngeal symptoms came on with great violence; for several days he was in imminent danger; and though we have succeeded in removing the disease for this time, still we are not quite sure of his recovery. We have used the strong muriatic acid on the authority of Bretonneau, who states, that he has not found any application so useful in diphtheritis; and as far as I have seen of its use in this hospital it seems to be a remedy of the greatest power.

There is another source of danger in this complaint, connected with its peculiar nature, namely, that it is not amenable to the ordinary

resources of antiphlogistic treatment. We find local or general bleeding, blisters, purgatives, or antimonials of little avail, the only means we possess of combating the disease, are those recommended by Bretonneau, and I must repeat, that from the result of the present case, and a few others which have occurred in this hospital, we have no reason to doubt the efficacy of the application. It is a fortunate circumstance, indeed, that we can avail ourselves of a remedy so simple and valuable when disease appears in so threatening a form, and our ordinary resources are found to be so feeble and inefficient. I beg of you to hold this case in memory; and if during the progress of some acute disease your patient should get a violent attack of laryngeal cough, and on examining the throat you find the characteristic membrane of this inflammation present, take the alarm immediately, and have recourse to the application of Bretonneau. Fix a piece of lint on a gum elastic catheter, or some other appropriate instrument, and having dipped it in the strongest muriatic acid, brush the whole diseased surface, and continue to do this daily, or oftener, until your patient gets relief. I shall bring this case again before you at a fit opportunity; our patient is better to-day, and has had no increase in his symptoms for the last thirty-six hours, so that I hope we shall be able to effect a cure.

It may be asked, was the diphtheritis in this case produced by the employment of tartar emetic? Without denying that this might be the case, I must observe, that no instance of a similar kind has occurred among the hundreds of patients who have been heretofore treated with tartar emetic in this hospital, and that it would be therefore not unreasonable to infer, that the disease in question has not been produced by it. There is one more remark which I wish to make before I quit this subject. Whenever you have a case of this kind to manage, be cautious in your prognosis; it shows a bad state of constitution, and you cannot tell how it may terminate. I have seen many bad diseases come after it; and the mere occurrence of such an affection is sufficient to prove a morbid state of the whole constitution.

Gentlemen, the next case on which I shall make a few remarks, is one at present in the chronic ward. The patient is a man labouring apparently under an affection of the larynx; he has aphonia to a great degree and some cough. I direct your attention most particularly to this case, because it is one of extreme interest, and involving several considerations with respect to disease and its treatment. What are the symptoms observable in this man? Cough of a laryngeal character, loss of voice, emaciation, and hectic. This is a combination, to which you will hear the name of phthisis laryngea very frequently applied. It is commonly supposed, by persons not conversant with pathological ana-

tomy, that we have a great many varieties of phthisis, and among the rest phthisis laryngea, that is to say, consumption depending on an affection of the larynx. More recent researches, however, have shown, that what has been termed laryngeal phthisis has on careful and accurate investigation often turned out to be phthisis pulmonalis. It has been proved, that in the great majority of chronic laryngeal affections, in addition to inflammation and ulceration of the mucous membrane of the larynx, the existence of tubercles in the lungs has also been discovered, so that when a case of the present kind comes before you, it is very probable that the patient is consumptive, although he presents nothing more than the symptoms of a laryngeal affection. This I believe is the opinion best supported by facts, and several of the most distinguished pathologists assert, that they have never seen the ulceration of the larynx without the co-existence of pulmonary tubercles. I draw your attention to this circumstance, as it is not generally observed or commented on by British practitioners, and yet, where is the intelligent practising physician who does not immediately perceive its importance? In a case of this kind, possessing such information we would not think of employing mercury, we would never have recourse to tracheotomy, nor would we adopt as therapeutic agents the severe means generally used. Surgeons are often not aware of the exact nature of this disease, or medical men in general. I remember having witnessed a case in which an error of this kind was committed; the patient was a gentleman, labouring under an inflammation of the mucous membrane of the larynx of considerable standing, which owing to some cause, was much exacerbated; he had been mercurialised for it, and when I saw him, he was like a person in the last stage of consumption. He had great rapidity of pulse, emaciation, hectic, and profuse expectoration. On applying the stethoscope, in order to satisfy myself, I found several large caverns in the substance of the lungs, which must have existed there for a considerable time. Now, any person cognisant of the fact, that most of these cases of chronic laryngeal disease are accompanied by pulmonary consumption, would certainly never think of employing mercury, which only accelerates the fatal termination of an incurable disease.

To persons unacquainted with pathology and medicine, it seems strange that diseases, apparently of so curable a nature, and particularly in their commencement, when the symptoms are only those of slight laryngeal cough, should prove so refractory to all modes of treatment; and this is apt to beget doubts of the efficacy of medicine. It is, however, no opprobrium to our art; the seeds of disease lie deeper and have been much longer planted than most persons are aware of; and at the very time when there are scarcely any phenomena

capable of exciting attention, except a mild laryngeal cough, and some slight wasting of flesh and acceleration of pulse, the structure of the lungs may have become extensively altered by tubercular development. I do not deny that the larynx may be the first seat of the disease, I only contend, that in a vast proportion of cases (of what is called phthisis laryngea), the primary affection has been the formation and growth of tubercles in the lungs; and that though in most cases the disease *appears* to commence in the larynx, still on closer examination we shall find that it is caused by pulmonary tubercles. What is the ordinary history of such cases? A medical man is called in to attend a patient who is labouring under laryngeal cough and sore throat; the case is set down as a chronic affection of the larynx in many instances, and the possibility of pulmonary complication is overlooked. Yet if you come to investigate such cases with accuracy, you will find, that previous to the appearance of symptoms of laryngeal disease, there were decided signs of pulmonary disorganisation. You will find, that at a period before the occurrence of his present affection, he had cough which was not of a laryngeal character, or he had spitting of blood, or some other symptom of disease of the lungs. I think we may safely lay it down as a general rule, that in all case of chronic laryngitis which have been preceded by pulmonary symptoms, there is every reason to suspect the existence of tubercles in the lungs.

This subject, gentlemen, is of importance also in another point of view; because in certain cases of disease of the larynx it is very difficult to determine with certainty whether the patient has an affection of the lungs or not. In some of these cases we have stridulous breathing, in others not; in some there is an obstruction to the entrance of air into the lungs, in others no such impediment exists. In those cases where there is a mechanical obstruction to the entrance of air into the lungs, we find that all the phenomena of respiration are masked, and it is extremely difficult to make a satisfactory stethoscopic examination. The air enters slowly and feebly into the lungs, its passage through these organs is marked by a corresponding want of intensity, and all the usual physical signs are rendered obscure. We may have a cavity in the lung, and yet the air will pass so slowly and feebly into the lung, that we cannot hear with any degree of precision the sound which it makes in passing through that cavity. There may be gargouillement, there may be cavernous râle, but we cannot hear them; all the signs of the different stethoscopic phenomena are almost entirely lost. Again, the patient is aphonic, and what is the consequence? We lose all the phenomena connected with the voice, we cannot examine the pectoriloquy or the resonance. The very sound of stridulous breathing obscures any other sound that may exist; so that many cir-

circumstances, as you perceive, render it very difficult in such cases to say positively that there are tubercles in the lung. *This, however, refers peculiarly to those cases where there is stridulous breathing*, for where this is absent, as in the man above stairs, we are better able to detect their existence, and in most instances can make a pretty satisfactory examination. But how are we to ascertain the presence of tubercular matter where the breathing is stridulous? This is a matter of difficulty, but by attending to the following directions you will (generally) be enabled to arrive at a proper diagnosis. In the first place we have a direct sign from percussion. The mere mechanical obstruction to the entrance of air into the lungs will not affect or alter the phenomena of percussion, and although the stethoscope is useless here, and gives us no certain information, we have a valuable auxiliary in percussion. If you should therefore meet a patient who has been labouring for some time under laryngitis, who has acceleration of pulse and wasting of flesh, and that on examination you find (the upper) portions of the chest dull on percussion, you may be almost certain that he has tubercles in the lungs. You must next inquire into the history of the case, and if you find that the laryngitis has been preceded by stomoptysis, or other pulmonary symptoms, your suspicions of the existence of phthisis will be more strongly confirmed. Lastly, if you take into consideration the very frequent complication of these two diseases, and combine all this knowledge, you will be able to make a correct and well-grounded diagnosis. You will discover on a careful examination that in most of these cases the formation of tubercles was antecedent to the occurrence of laryngeal symptoms. Remember this, therefore, in your prognosis, and you will never expose your patient to the torture necessary to remove a chronic laryngitis. With respect to the patient whose case I have been commenting on, it appears that he had symptoms of pulmonary disease before the laryngeal affection took place. He had first, as he states, hæmatemesis, then cough, and afterwards hæmoptysis. As he has no stridulous breathing, you can examine his chest more satisfactorily, and ascertain whether he has tubercles or not. You will find that he has distinct cavernous râle, that his voice is more resonant on the right side of the chest than on the left, and combining this with the existence of laryngeal disease, and recollecting that the pulmonary affection preceded that of the larynx, you may decide with certainty that he has consumption, and that the laryngeal affection is only an accidental complication.

There is a case above stairs under the care of Mr. Martin, which is exceedingly important in a practical point of view; the patient is a young woman affected with dropsy. This case illustrates well the truth of the proposition that dropsy is not to be generally considered

a disease *sui generis*, but as the result of some other disease, and that in order to effect its cure, we must carefully investigate its nature and ascertain its cause. The mere symptomatologist endeavours to remove it by the ordinary means, but we must accurately explore its cause, before we can hope to treat it with success. The history of this young woman's case is, that she had, some time since, an attack of acute peritonitis, that on the subsidence of this she had diarrhœa, and again symptoms of subacute inflammation of the peritoneum. She also had an attack of bronchitis, and afterwards became anasarcaous with enlargement of the belly. Here, gentlemen, we have here in the first place inflammation of the serous membrane of the digestive tube, then of its mucous coat, and afterwards of the membrane lining the respiratory apparatus. Considering the origin of the complaint as consisting in a subacute peritonitis, we determined to treat it accordingly; she was bled, leeches, and blistered, and then we had recourse to iodine. We are rubbing with iodine ointment, and she is taking internally one grain of iodine and eight grains of the hydriodate of potash daily, dissolved in two pints of distilled water. This solution, called the iodine mineral water, is an excellent remedy, and under its use you have seen that the size of the abdomen has been very much reduced, and the patient materially improved. In cases of this kind I have witnessed numerous instances of the value and efficacy of iodine, and can recommend it strongly. A medical gentleman related to me some time back the particulars of a remarkable case of the wife of a respectable person who had ovarian dropsy to such an extent that her life was despaired of. Her belly was so enormously swelled, that at first sight he thought she had pillows over it. As he was called in, he, of course, wished to do something, and having recommended the employment of iodine mineral water, went away, leaving, as he thought, the woman to her fate. Some weeks after this, her husband called on him to express his thanks for the relief he had afforded her, and stated that she was amazingly improved. He had forgotten the case, and wished to see her again. He found her up and dressed, the abdomen quite soft and compressible; there were, as well as he could ascertain, some floating tumours in it, but the enormous dropsical swelling had almost completely subsided. It appeared that some short time after she began to use the iodine, a copious diuresis came on, and since that time she has been in the enjoyment of very tolerable health, and though while she has those tumours her life is insecure, still no one, I think, will deny that existence has been prolonged and much good effected. It is my intention to give iodine a full and fair trial, and to ascertain its comparative value in the treatment of dropsy. There is a patient at present in the male ward, who has enlarged liver and spleen with ascites; he is using

the iodine mineral water, but as yet has received but very little benefit. We shall however continue its exhibition, for it is frequently necessary to persist in the use of this remedy for a considerable time and never give it up in despair until thoroughly convinced of its inefficacy.

CLINICAL LECTURES,

DELIVERED AT THE

HOTEL DIEU, IN PARIS,

During the Session of 1832-33.

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

Of Strangulation at the neck of the Hernial Sac.

It was believed for a long time that in inguinal hernia the strangulation depended on the constriction at the ring on the intestine. This erroneous opinion has had frequent fatal results. Acting on this false principle surgeons were in the habit of freely unbridling the ring and returning the strangulated portions into the belly, believing the strangulation to have been freely relieved; ill effects, however, were the invariable result of this, and the patients sunk without the real cause of death being known.

These unfortunate results which I have frequently witnessed after hernial operations, said M. Dupuytren, fixed my attention to the subject, and led me to research upon them, and I reflected that the ring was not the only seat of the strangulation, and the dissections I made proved to me, that in the greater number of cases, the neck of the hernial sac was the cause of the injury. Time has verified the truth of my ideas upon this point, and I believe I can now state it as a fact, that in nine cases of strangulation, eight of them are caused by constriction at the neck of the sac. Remember that my observations apply specially to inguinal hernia, for this disposition to strangulation is less common in crural and umbilical herniæ, the structure of the parts concerned in these latter will explain this difference. But that this subject be well understood, it is necessary to define what is meant by strangulation. No idea is more exact than that which defines strangulation as the action an ordinary or foreign body, which presses of with greater or less force on all parts within the sphere of its activity. The results of this pressure may be naturally deduced, the action of the parts is augmented, the functions of life within them are in an altered state, or they may be effaced and gangrene may ensue. Strangulation may take place in many parts, but it exists more generally in those places where openings exist, in which the parts may be engaged, in particular the inguinal ring and crural arch.

Amongst the different species of strangula-

tion, some are external, others are internal. I have observed fifteen species of this latter, but in general the greater number are external. Art can only be rendered available in external strangulations; there is but little resource against internal ones. But between these two species there occur some which may be called mixed, such as those which result from a hernia being reduced *en masse*. Some years since the body of a woman was brought to the amphitheatre, externally there was nothing remarkable seen, but on the abdomen being opened, a tumour formed of intestine was found behind the crural arch, of the size of half a fist; its colour was of a livid red and a portion of epiploon was in the hernial sac. On examining the tumour a knuckle of intestine was found in a state of gangrene; the strangulation was at the neck of the sac. I learnt that two days before, this woman had been affected with symptoms of strangulation, attempts at reduction were made, the hernia returned, and was supposed to be reduced, when some accidental symptoms supervened; all efforts were unavailable, and she sunk in a short time. In other cases I have met with species of internal strangulation, the primitive causes of which were in the abdomen. In a person afflicted with hernia unequivocal symptoms of strangulation showed themselves. I performed the operation, but I found only a portion of epiploon in the sac. I drew the intestines outwards, and found that the strangulation existed internally towards the pubes. I drew it towards me, divided it, and the patient recovered.

But how does the strangulation of the neck of the hernial sac happen, and what are the anatomical conformations favouring its production? When the intestine is pressed forward, it pushes the peritoneum before it, forming a species of funnel, of which the pointed portion is directed downwards, and broader portion upwards; but that the tumour may not press further down, the relative situation of the parts becomes changed, and the broader funnel-portion presents downwards. This change is caused by the situation of the ring, the opening into which is so narrow as not to be more than four or five lines in diameter. In proportion as the hernia is augmented in volume, the neck of the sac is gathered up into folds by its weight, and by the tendency of the displaced peritoneum to return upon itself, a tendency which likewise shows itself in the obliteration of the tunica vaginalis in children, and in the form of the epiplocele—small near the ring and large at the base of the sac. But the principal cause of this circular-formed groove, and of this contraction of the neck of the sac, arises from the application of bandages over the hernia; the compression of these over the neck of the sac tends to pucker, contract, and even inflame it, as well as the cremaster muscle and cellular tissue, causing a retraction and structural formation, which if not fibrous, is

at least very resisting; the neck of the sac may even become cartilaginous.

The diameter and anatomical character of the sac contribute to favour strangulation. Indeed, in the greater number of cases the opening is scarcely more than four or five lines in diameter; its edges thin and sharp, and formed by the refolded peritoneum, render the strangulation more dangerous than when at the ring, which does not act so strongly on the intestine. There is, however, an anatomical disposition strongly facilitating strangulation at the neck, which is this: the relative state of those persons in whom the testicle descends at a later period of life, and gives rise to the formation of a vaginal hernia, for the word "congenital" applies only to herniæ at birth. Examine a vaginal hernia, and you will constantly find the parts thus disposed:—the orifice through which the protrusion takes place is narrow, the edges are sharp; below you perceive the neck, the inguinal ring, and the species of ampulla in which the hernial intestine is contained, having their ordinary dimensions. If you then draw the intestine into the sac, you find the strangulation formed of itself, and you can understand from seeing this what takes place during life.

We have been presuming that the strangulation occurs in the majority of cases at the neck of the sac, we must now consider whether this neck be fixed or moveable. Observation demonstrates that it is always moveable, because the elements entering into its composition are united to the neighbouring parts by very loose cellular tissue. The soft adhesion of these parts to each other, and the little union they have with the aponeurotic openings, explain the facility with which the hernia may be reduced and brought down again.

Are there any symptoms diagnostic of the existence of strangulation produced by the neck of the hernial sac? Most certainly there are. And we may also add, that the symptoms differ from each other. Large herniæ are less frequently strangulated at the neck than cylindrical ones. Those herniæ, however, which follow this disposition the most frequently are congenital herniæ.

The circumstances tending to verify a diagnosis are these:—whenever the strangulation is at the neck, the whole, the half, the third, or the fourth of the strangulated parts may be returned without any noise, and may be made to come down again; added to this, however, the hernia must be cylindrical, the inguinal canal must be large, and the peritoneum non-adherent. It has happened in about forty cases, that such herniæ have been completely returned, without, however, their remaining so. If the tumour were at the ring, in the canal, or at the superior orifice, it could not be thus moved, because the parts are nearly inflexible, whilst the neck, on the other hand, is extremely moveable, on account, as

has been before said, of the lax state of the parts. Before going further it must be added, that this apparent reduction should put practitioners on their guard, because in these cases the strangulation always continues. In a case of this kind, every known means must be employed to reduce the tumour; if these should fail, the ring must be divided, and the intestine drawn from above downwards. I have been obliged, in more than ten cases, to have recourse to this plan, and always with success.

In cases of this kind the tumour is tense; and, by percussion, we may always recognise, by the seat of pain, where the hernia is situated. In this manner, after an operation, we may detect the spot where the portion of intestine has been returned, on account of a peculiar sensibility felt over the part. Thus the situation of the tumour and the seat of pain announce where a hernia has been reduced.

When the strangulation is at the ring, that is, at the lower part of the inguinal canal, the hernial tumour does not extend above this point, the canal is empty, soft, and indolent to the touch, and the ring feels hard, stretched, and tightened. On the contrary, when the strangulation is at the neck of the hernial sac, that is, at the superior orifice of the inguinal canal, this canal is always hard, full, and painful, and gives to the touch the sensation of a cylindrical tumour situated from above downwards, and from within outwards. It is sometimes impossible to insinuate the finger between the displaced parts and the ring. In some cases the strangulation exists in the whole length of the canal, and it must be unbridled from one end to the other, and over its superior surface. Sometimes there are two strangulations to relieve instead of one, with a little tightening at the ring, and a stronger constriction at the neck of the sac.

When the sac is very moveable, and may in part be returned into the abdomen, the strangulation sometimes mounts more or less towards the upper termination of the inguinal canal; and it may sometimes exist further from the ring than this, when the hernia is reduced *en masse*. We are thus led, by a natural transition, to speak of those strangulations which occur in the abdominal cavity. These are more dangerous. The reason is easily discovered, the situation of external strangulations is known, and the accident follows a certain course; there can be, therefore, no error as to the diagnosis; whilst, on the other hand, internal strangulations have no fixed situation. This formation does not depend on certain organic dispositions, but on accidental and very varying circumstances. There is, however, a species of internal strangulation, which may be termed *mixed*; it is the most common one, and is easily known; it is that which follows the reduction into the abdomen of herniæ strangulated by the orifice of the neck of the sac which contains them.

It may be objected, perhaps, that these distinctions are useless, the answer to this is easy. I will suppose an individual has a strangulation at the neck of the hernial sac, and that the inguinal ring is divided, the strangulated parts will of course be immediately returned; this occurred at an operation at which I assisted, and I must add, that I had some doubts as to its success. The bad effects of the strangulation still continuing, peritonitis was feared. The patient died, and on opening the body after death, the cause of the injury was found to be at the neck. The ring had been laid open, and yet the parts had remained strangulated. This shows how highly necessary it is to know the precise seat of the strangulation. In discovering this, it will be necessary to draw the intestine towards itself and carry the finger along the hernial portion of the intestine, to discover the precise nature of the obstacle.

Does the strangulation at the upper part of the canal differ from that at the lower? Yes it does, as in the first instance; the parts are sooner liable to become mortified, as the borders of the superior orifice are so thin that they strongly compress on the neck of the hernial sac, whilst the inguinal ring being larger, and the edges not so tense, the strangulation is less in degree, and the intestine therefore not so forcibly compressed. The comparison drawn from a ring will easily show this difference. Thus, if you take a large ring, it makes no compression on the parts contained in it, but if the edges are sharp and cutting it presses narrowly on the organs. Strangulation at the neck of the hernial sac soon producing disorganisation of the parts, the operation for its relief should be immediately done, because the reduction of the hernia is with difficulty accomplished entirely, and because the cutting edges on the intestine keep up a constant cause for mortification. We must here notice something of the resistance of the tissues implicated; the peritoneum will sustain the pressure the longest, but the mucous membrane may become divided around; if the strangulation has lasted two or three days, the cellular membrane will then become divided, and finally in some cases the peritoneum will be cut through, so that the slightest traction will divide one portion of the intestine from another. In operating therefore on such herniæ as these, the intestine must not be drawn upon before the parts have been freely laid open, for but one portion of intestine might in such cases be drawn down, and effusion might occur into the abdomen.

ON CUPPING GLASSES.

BY JONATHAN OSBORNE, M.D.

ONE word on cupping glasses. Those which have broad spreading edges are

far inferior, both in convenience of application and in power of preserving a vacuum, to those with perpendicular edges. In using glasses it frequently happens, that the rarefaction of the air is carried too far, and the suction becomes so great as to stop the circulation of blood through the part, and prevent the bleeding. This especially happens in cupping the abdomen and other soft parts. There should always be an assortment of cupping glasses, with oval and other shaped mouths, in order to be applied as occasion may require. By attention to these particulars, cupping may be rendered of much more general application than heretofore; and in public institutions where economy is an object, a great saving in the article of leeches may be effected.—*Dub. Journ.*

A TRANSLATION OF BARON ALIBERT ON DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

WITH such exceptions as I shall point out, the *teignes* of M. Alibert, with which I begin, correspond with the different forms of porrigo, according to the nomenclature of Willan and Bateman. With respect to the origin of the latter term, I shall be content to refer my readers to the writings of these authors. It was considered to be a better designation than that of *tinea*, or *tinea capitis*, probably because the use of the latter tended to encourage the absurd notion that the disease was produced by an insect or ringworm: that is, a worm burrowing in the skin, following a circular course, its ravages being marked on the surface by circular spots on which the hair had been destroyed.

Whether the terms *teigne*, *tinea*, or *porrigo*, however, are employed, it will be found, as we proceed, that though they may serve as landmarks to direct the student in his reading of what has been written, they have no other merit. They denote nothing of the essential characters, nothing of the causes, nothing of the pathology, of

the disease ; and they are all liable to these serious objections—that they assemble, under one head, diseases of entirely local origin, which are contagious—diseases of the most manifestly constitutional origin not contagious, and of a decidedly salutary nature—and diseases which are the mere results of the irritation of filthy lodgments on the skin impeding its healthy actions.

Baron Alibert's work is professed to be, and undoubtedly is, a practical work. "I write what I have observed," says he, "regarding little what has been said before me." In this book he makes age no small recommendation.

SECT. I.—*Facts relating to the particular history of the Teignes.*

SPECIES I.—*Teigne faveuse—Tinea favosa**.

This species of teigne shows itself in the form of scabs, or crusts, of a yellow colour, sometimes isolated and circular, sometimes approximating so nearly as to form large plates of scab on the scalp. Each circular scab is depressed in the centre like a saucer, the border elevated around, which gives it some resemblance to the cells of a beehive.

The favous teigne develops itself by very small pustulous pimples, which create an itching more or less violent on the scalp. These pimples contain a purulent matter, which dries up and gives place to the formation of several crusts, hollow in the middle, the dimensions enlarging successively, and still preserving the circular form which belongs to them. As these pimples sometimes show themselves in great numbers on different parts of the head,

they join each other by the edge to the point of forming by their aggregation plates of a considerable extent, in which the eye, nevertheless, distinguishes with facility the cup which characterises more particularly the favous teigne. This cup bears some resemblance to the cells of a beehive, or the fructifications of lichens which cover the trunks of certain trees. When this chronic exanthema is not very old, the crusts are sometimes of a yellow, sometimes of a pale red colour ; but as these same crusts get old and dry, they become white, wear off, break, and detach themselves from the hairy skin, and then you only perceive on the head the remains of the favous scabs, which cease to assume a regular form.

The scales or scabs of the favous teigne have their bases chiefly encased in the cutis, and are strongly adherent to it. Indeed I have often wished to separate some of these from the skin, in order to preserve them, being in the habit of doing so in several cutaneous diseases ; but I never could succeed without affecting sensibly the scalp, and producing a discharge, more or less considerable, of blood. The *T. favouse* carries its ravages very deep into the scalp, which cracks, and sometimes an ichorous, sometimes a purulent, matter runs from the crevices, which result from the progress of the disease. It destroys the skin, and, by ulceration, sometimes exposes the bones of the skull ;—this last case is, however, very rare. With some individuals, the favous crusts do not confine themselves to the head ; I have seen them appear on the forehead, the shoulders, the temples, the lower part of the shoulder-blades, the elbows, and the fore-arms. I have seen them extend from the top of the loins to the sacrum, on the front of the two knees, on the external and upper parts of the legs, &c. ; in short, it appears that all the places where the cellular structure is hardest and thickest are subject to them. The itchings created by the favous teigne is, from the number of

* The *porrigio lupinosa* of Willan and Bateman is a totally different disease from the *porrigio favosa* ; it is, in truth, only the common ringworm of England, where the morbid secretions have been suffered to grow and accumulate without those interruptions which cleanly mothers and nurses deem to be their first duties towards children. Even if a reward were to be offered, it is more than probable that a case would not be found in England to correspond with Baron Alibert's description in all its parts.

the pimples, sometimes intolerable. From that time the children are induced to scratch themselves, and the sensation of itching or smarting is so intolerable, that they find a kind of voluptuous enjoyment in tearing the scalp with their nails. The lice which multiply in great quantities under the crusts add further to this torture. All the cavities are full of them, and the surface of the scalp, and the mass of scabs are so occupied by them, that they appear agitated with their movement. The smell emitted by this disease is as disgusting as its aspect. This smell which has more or less power, always preserves the same character. I have often remarked to my pupils that it resembled greatly the urine of a cat, or those apartments which mice have a long time infested with their presence. When by the help of emollient poultices, the favous crusts fall off, this smell changes its character, and has in it something insipid and nauseous. Independently of the favous scabs, which we have already described, you can see in the intervals which separate them, the surface of the scalp covered continually with furfuraceous scales, which are produced by the general irritation of the scalp. We have often proceeded to the examination of the scalp after the fall of the crusts, which have been softened by repeated lotions and poultices. It is then you see the reticular structure, red and erythematous; the epidermis has disappeared, and a yellowish viscous and foetid liquid runs here and there from numerous ulcerations. You may likewise perceive a greater or less number of small dispersed abscesses level with the scalp, sometimes, but not generally, taking a lenticular form, and appearing like so many centres of inflammation. But one of the most remarkable symptoms of the favous teigne, when you neglect it, and abandon it to its progress, is the alopecia that I have seen become almost universal. With certain individuals, in the places where the hair has been rooted up, the skin remains

smooth and shining on the surface. You may perceive, notwithstanding, here and there some thin hairs altered in their structure, as well as their colour, and offering a lanuginous appearance. I could mention some concomitant symptoms of the *T. favouse*, such as the obstruction of the cervical glands, the swelling of the cellular structure, the tumefaction of the skin in certain places, &c., but in addition to those symptoms not being constant, they are common to different kinds of scald head. I must not, therefore, swerve from the exact plan which I have imposed on myself by loading this description with superfluous observations.

CASE 1.—Isidor Lignon, aged five, was born of healthy parents, having been nursed by his mother, he enjoyed excellent health; in order to be able to attend better to domestic occupations, she confided him to the care of an old woman, who had been afflicted a long time with a favous teigne. The child lived near a year with the woman, and even slept with her. At the end of this time there appeared on different parts of the head yellow circular crusts, depressed in the centre and raised at the edges. This disease increased to so great a degree, that crusts united and formed one entire cap, which covered the scalp; each crust presented the form of a small cup, and even in the places where they were the closest, the confusion and number did not prevent the true character of the favous scab from being distinguished. In the small spaces which were not covered with crust, the skin was red and inflamed. The itching was great, and when the child eagerly gave himself up to the pleasure of scratching, he took off the scabs, and underneath there appeared a red and foetid sanies.

CASE 2.—Virginia and Julia Calendini, seven and five years of age, appeared with their heads covered with the scabs of this disease, of the usual colour and cupped form, the

greater part united at their edges with others, making an encrusted mass. Fissures and crevices occupied by lice, and a stench unbearable disgusted the senses of sight and smell beyond bearing. These children were cured by means we shall hereafter detail.

I have given these cases as specimens of the observations; if all were translated and printed, they would occupy too much of the pages of the Journal, to be consistent with its best interests.

SPECIES 2.—*Teigne Granulée*—*Teigne Granulata*.

The crust of this kind of teigne forms small lumps or grains, of sometimes a grey and sometimes a brown colour, of a very irregular and unequal shape; these have no excavation or hollow at the top, which clearly distinguishes them from the preceding kind.

The granulated teigne does not in general occupy so large a space of the scalp as the favous; it most frequently comes on the upper and back part of the head; it is composed of small brown or dark grey crusts, which resemble sometimes fragments of mortar, coarsely broken, or plaster fallen from the walls, which has been dirtied by damp and dust. These granulations have not in any case their surface hollowed in the centre; they are embossed and angular at the edges, like the seeds of certain plants; in short, extremely irregular, they are often very hard, and have a strong consistence, which poultices cannot soften. As the scalp of children covered with these scabs is extremely rough to the touch, we at first nominated it *teigne rugeuse*, in union with Monsieur Gallot. But this denomination is very vague; that of granulated teigne, which I adopted at last, is more suitable to express the kind of affection which I propose making known here. It is known vulgarly by the name of *galons*.

These crusts, which generally are a little distant from each other, are

not so deeply encased in the dermoid system as those of the favous teigne; but sometimes like them they are surrounded by a pretty considerable number of thin scales, dry and furfuraceous, which are here only an accessory symptom arising from the irritation of the skin. The granulated teigne has a nauseous smell, which greatly resembles rancid butter, or milk which is beginning to turn. This smell is particularly perceptible when the crusts are damp, and when there is a considerable discharge from the surface of the head, but it disappears as soon as these same crusts arrive to a complete exsiccation, and acquire a hardness which makes them resemble a gypseous or chalky matter.

The itching created by the granulated teigne is very great. When the crusts are separated from the scalp, the places they occupied remain red and erythematous; they are smooth, and polished, often swollen. Here and there may be perceived very small whitish abscesses, which are level with the scalp, and from which issues a small quantity of viscous colourless liquid, or a whitish matter, which thickens and dries from coming in contact with the air, and thus causes new crusts to spring up analogous in form and colour to those already fallen.

The granulated teigne scarcely ever attacks the different parts of the body like the favous, it confines itself at furthest to the face. I have seen it in some cases occupy the forehead near the hair, the eye-brows, the lateral parts of the nose; but this is very rare. I have further remarked that adults scarcely ever have this disease. I observed, however, two young girls who had arrived at puberty with it.

CASE 1.—Adelaide Bonne, aged four, of a melancholy constitution, and a brown skin, of unknown parents, had the small pox, and experienced no croup in her infancy; she had been afflicted at the hospital

St. Louis with an affection of the scalp, which presented the following symptoms:—Crusts of a brownish grey particularly fixed on the summit of the head and the back parts of the neck; these crusts, in some spots wide apart, in others approaching each other, and in consequence being confused, unequal, and irregular in their form resembled fragments of blackened mortar; there were grains of this matter glued to and suspended by the hair. In the other parts of the head were scales or thin crusts. At the base of the occiput there flowed a viscous humour, which glued the hair together; its smell was unpleasant, like milk or spoiled cheese, but bore no analogy with that of the favous form.

SPECIES 3.—*Teigne Furfuracée*.—*Tinea Furfuracea*.

This form does not produce crusts, but furfuraceous scales, white, more or less thick, sometimes damp, and adhering to the hair by the help of a viscous and foetid discharge, and sometimes dry and friable, detaching itself from the head with the greatest facility.

Description of the Furfuraceous Scald Head.

This affection is known under the name of *T. porriginæ*. We have studied it with rigid attention. It begins by a slight desquamation of the epidermis of the head, often accompanied by a considerable itching; an ichorous matter flows at the same time from the inflamed reticular structure, which attaches itself and forms by drying on the hair a more or less considerable quantity of scales. As this disease increases, by degrees it spreads over a large part of the scalp; these beds of scales thicken, their margins are of a whitish colour, sometimes reddish; in short, they resemble a heap of bran or coarse flour. When there is no fluid discharge, the scales fall off by the least friction exercised on the head. The cutis being cleared of the scales, we

have observed it was bereaved of its epidermis, that it was of a pink colour, and offered a smooth polished and shining surface like varnish. The furfuraceous teigne is not very common in hospitals, and that is undoubtedly the reason why several authors have refused to admit its existence. As it has been seen several times complicated and co-existent with the granulated and favous forms, it has been thought that it might be only a degree less advanced of these. To an accurate observer, however, the scabs which characterise this exanthema are of quite a different kind; besides, they glue and mat the hair, and form beds, which no other species do. When a finger is put on these beds they yield softly to the pressure. In some circumstances it is not merely the scalp which the *T. furfuracea* attacks. I have seen it with some children advance to the forehead and form plates which resembled heaps of bran, and often equalled snow in the whiteness of their particles; it has extended even to the eye-brows. Authors who have treated of the furfuraceous scald head in their works pretend to have observed it attack different parts of the body; but it is an error which proceeds from their having confounded this affection with the furfuraceous and squamous dartie. The furfuraceous scald head excites a considerable itching on the scalp, and generally maintains a great quantity of lice. It is accompanied with a certain phlogosis, which gives place to the formation of small vesicles or ulcerations on the skin; it is then damp, and exhales a glutinous humour, which has the smell of sour milk; at other times it is dry and quite inodorous. I have never observed the furfuraceous scald head attack adults, but it very often happens to children who have passed their first septenary, although a contrary opinion has been advanced.

CASE 1.—Lucie Colin had attained the age of six, when she was first attacked. She was endowed with a

bilious sanguine constitution; her skin was white, her hair chestnut colour; the disease affected the fore and hind-part of her head; it was a mass of furfuraceous scales, of a yellowish-white, other times greyish, and so dry that the most simple touch sufficed to make them fall in numbers on the child's shoulders. This exanthema did not emit any fœtid smell; there was a great itching, which was occasioned by the presence of scales and lice, with which this affection abounded; the places on the head without scales were smooth, red, and much irritated.

(To be continued.)

RESEARCHES ON THE DIAGNOSIS OF PERICARDITIS.

BY WILLIAM STOKES, M.D.

IN a former paper I announced that in several cases I had been enabled to verify the diagnosis of Collin, relative to the sound of friction, produced by the rubbing together of the surfaces of the pericardium; when they are covered with lymph, which sound he compared to that of the creaking of new leather. I also stated, that the character of this sound varied in a remarkable manner, not only in different cases, but also in different stages of the same case; that in some cases it closely resembled the *bruit de soufflet*, produced by vascular disease; that there was the most complete analogy between it and the *frottement* of Laennec, as arising from inflammation of the pleura; and that the observation of this phenomenon would be found an important addition to the direct signs of pericarditis. Since that period, I have been so fortunate as to meet with several cases of pericarditis, all of which I have studied with the greatest care, both as to their symptoms and stethoscopic phenomena; and I can now announce, that in many cases of this disease the diagnosis can be drawn from direct signs with extreme accuracy, so that it can no longer be stated to rest chiefly on negative evidence.

CASE 1. *Violent symptoms of an inflammatory affection of the chest; sound of friction over the heart; healthy state of the lungs; pericarditis.*—A young man, named Keas, æt. 20, was admitted into the Meath Hospital about the middle of January, 1830, labouring under symptoms of gastric fever, and complaining of severe pain in the inferior sternal region, which symptom subsided in the course of a fortnight under antiphlogistic treatment. He was again admitted on the 18th of February in a state of great distress from constant short cough, hurried and difficult breathing. He had inflammatory fever, rapid, small, and weak pulse, and great tenderness of the integuments of the chest. These symptoms had been of four days' standing. The anterior portion of the right side presented a considerable degree of dullness on percussion; but, with the exception of this sign, there was no other physical indication of thoracic disease. He complained of some pain in the lower portion of the chest. On the next day he complained of acute pain under the false ribs of the right side, where he said all his pain was fixed; his pulse was very rapid, and irregular in fulness and frequency; respiration 48. The following day respiration was found to be completely thoracic; yet even at this period no stethoscopic sign of pulmonary disease could be detected, sufficient at all to account for his symptoms.

The patient was somewhat relieved on the morning of the 20th, but in the afternoon was seized with a violent stitch under the left mamma, which continued until the middle of the night. On the following morning the pulse was extremely intermitting and irregular; the heart's action was strong, accompanied with a peculiar rustling sound, conveying the idea of two exceedingly rough surfaces rubbing one upon the other, and accompanied by a feeling of friction when the hand was applied over the region of the heart. The patient sunk in the course of the night, no treatment

appearing to have had any effect in removing or even indeed alleviating the severity of his symptoms.

Dissection.—Body somewhat emaciated; the heart was found greatly enlarged, extending to the right side, and extensively displacing the lung. The internal surface of the pericardium was found, as it were, completely mamillated by depositions of semi-cartilaginous lymph, and near the apex of the heart a strong cartilaginous band, nearly an inch in width, was found connecting the heart to the external fold of the pericardium. Besides these appearances, which were evidently the result of chronic disease, a recent effusion of lymph, of the colour of blood, was found forming a feeble and soft medium of union between the heart and pericardium; valves healthy; some cadaveric engorgement of the lungs, which were in other respects free from disease.

In this case the nature of the disease was not suspected until within a very short time previous to its fatal termination. As the patient was of a strumous habit, my first idea was that it was a case of acute phthisis, an opinion which I afterwards forsook from the absence of stethoscopic signs of pulmonary irritation which so constantly accompany this affection: in fact, the stethoscope detected nothing but intense puerility of respiration, with some slight bronchial râles. It was but a very short time before death that the pulse became intermitting, and at this time the phenomena of the heart, as noticed in the case, were detected; but I am not at all prepared to say that they might not have existed before, as one of the most curious circumstances connected with these phenomena is *the very slight distance beyond the actual situation of the heart to which they are perceptible*. The dulness of sound of the right anterior portion of the chest was evidently caused by the great enlargement of the ventricle and auricle, and was an additional

circumstance tending to mislead in the diagnosis of the tubercle.

CASE 2. Extensive empyema of the left pleura; displacement of the heart to the right mammary region; acute latent pericarditis; nearly complete obliteration of the pericardial cavity before death; intense sound of friction disappearing in the progress of the obliteration.—A man named Lennon, ætat 28, was brought to the hospital early last January, labouring under the most aggravated dyspnoea. On examination I detected an extensive empyema of the left side, and the heart was observed to pulsate to the right of the sternum, but presented no morbid sound whatever. His symptoms had been at least of four months' standing, and he stated that he had observed the displacement of the heart a month previous to his admission.

On the following day his breathing was much relieved, and he was placed in the medical wards under the care of Dr. Graves. He was treated by local bleeding and counter-irritation, towards the end of the month he suffered much from the supervention of bronchitis, which was greatly relieved by extensive dry-cupping and the use of the tartar-emetical solution. By the end of the month it was found that the dilatation of the side was considerably less.

On the 1st of February the patient came under my care, the displacement of the heart continuing, *but without the occurrence of any morbid sound in its pulsations*. The patient was treated by mild mercurials and narcotics. In the course of the week he began to suffer extremely from flatulent distension of the belly. On the 10th I made a careful examination of the whole chest, no change whatever was observed in the stethoscopic phenomena or impulse of the heart, but on the 12th having placed my hand accidentally over the displaced heart, I was astonished at feeling a most distinct fremitus over the entire region, giving to the hand a sensation of two very rough surfaces

rubbing violently one upon the other. On applying the stethoscope, we found that the sound varied over different parts of the heart. At the base the sound was similar to the *frottement* in ordinary cases of dry pleurisy, but towards the apex, it closely resembled the *bruit de râpe* of Laennec, its point of greatest intensity being between the upper border of the third and lower of the fourth rib. We observed also that if the stethoscope was moved to a distance of not more than an inch and a half from the situation of the heart, these remarkable phenomena ceased, though the contractions of the heart were heard distinctly. Pulse about 130, small but not at all irregular; the sound of friction accompanied both sounds of the heart; dyspnoea very urgent, but the patient made no complaint whatever as connected with the heart. The region of the heart was freely leeches, and the patient ordered digitalis.

13th. The *fremissement* is remarkably diminished; the sound is generally quite analogous to the double *bruit de râpe*; heart's impulse less; no increase of dullness on percussion. From this period till the 17th the sensation and sound of rubbing gradually disappeared; it was only by close questioning that the patient admitted he had some pain at the right of the sternum.

On the 18th all *fremissement* had disappeared, except in a spot which could be covered by the stethoscope, over the base of the heart and to the right side; in this situation a sound between a *frottement* and a *bruit de râpe* was distinctly audible. The patient sank on the 22nd.

Dissection.—The left pleura presented the usual appearances which occur in extensive and chronic empyema, its cavity containing nearly a gallon of sero-purulent fluid. The right pleura contained about a pint of perfectly clear serous fluid, and presented no effusion whatever of lymph on its surface. The peri-

cardium appeared increased in size; it had lost its semi-transparency, and could not be made to glide over the heart. On opening its cavity, we found, with the exception of a small space at the base of the heart, exactly corresponding to the situation where the *frottement* was last heard, that it was completely obliterated by recently effused lymph, which was reddish, and though soft, presented a considerable degree of consistence, so that when the two folds were separated by traction a vast number of layers, perpendicular to the surface of the heart, made their appearance. On the anterior portion of the ventricles towards the apex, the union of the two surfaces was complete. Here the quantity of effused lymph was evidently much less than in other parts of the cavity. Around the origins of the great vessels, particularly towards the right side, no union had taken place between the surfaces of the pericardium; each face, however, was covered by lymph, presenting a considerable consistence, and giving the appearance which is produced when two smooth surfaces covered with tenacious matter are suddenly separated.

This case I look on as one of extreme importance, as it was the first in which the positive diagnosis of an effusion of lymph on the surface of the pericardium was verified by dissection, and it must be recollected, that the heart was extensively displaced by an empyema, and that the patient scarcely, if at all, referred any uneasy sensation to the situation of the recently suffering organ. The diagnosis was founded on the following circumstance:—first, the sudden appearance of the phenomenon of *fremissement*, and the sound similar to the *bruit de râpe*, in a case which had been long under accurate observation, and which presented no such signs two days before their first appearance; secondly, the similarity of these phenomena with those in the case of Keas.

But in the progress of the case

there was added to the diagnosis, and I recorded it as my opinion, that adhesion of the surfaces had taken place except over the base of the heart. This diagnosis was arrived at from observing the rapid subsidence of the phenomena under treatment, except in the above situation, *the region of the heart still continuing clear on percussion*, a proof that the disappearance of the signs was not owing to a liquid effusion, which opinion was still further rendered probable, by the impulse of the heart continuing to be felt with the utmost distinctness.

(To be continued.)

THE IRISH INFIRMARY AND DISPENSARY ACT.

OUR readers will recollect our animadversions on the draft of the Irish Infirmary and Dispensary Act, as passed by the House of Lords, which proposed, that the Lord Chancellor, bishop of the diocese, and rector of the parish in which any hospital or dispensary was to be established, should form a corporation, with perpetual succession, and so forth, to found, establish, and supply all vacancies in the same. We offered such strictures on, and objections to, this measure as we deemed unanswerable, and we are proud to state that the House of Commons acted on our suggestions, and expunged all the objectionable parts of the bill. The original act was calculated to destroy the institutions for the benefit of which it was intended. It was a narrow exclusive piece of legislation, which might have been tolerated three centuries ago, but was unsuited to the spirit of the present times.

There are two clauses (6 and 7) in the act as it stands that are decidedly beneficial, the power of enforcing subscriptions, and suppressing bribery at medical elections. We are confident that Mr. Hume and Mr. Warburton will insist upon the introduction of the last into the new law for regulat-

ing the education and practice of the medical profession in this country, which will most certainly be enacted during the next session of parliament.

The bribery at medical elections in London is the grossest that can be imagined. The candidates for the offices of physician or surgeon to London hospitals are appointed by family influence, relationship, or apprenticeship; while those for dispensaries very generally go to the treasurer the evening before, and make from fifty to five hundred governors or voters, and in this way persons who are totally disqualified, or, at least, infinitely inferior to the other candidates, get appointed. We could adduce a hundred instances of this kind. If this system be decreed objectionable in Ireland, we cannot comprehend how it can be otherwise in this part of the kingdom. We are extremely glad that the law has abolished it in Ireland, as this will be a precedent for the next parliament.

A BILL, intituled, "An Act to explain and amend the provisions of certain Acts for the erecting and establishing Public Infirmaries, Hospitals, and Dispensaries in Ireland."

"Whereas it is expedient that the provisions contained in certain acts relating to the erecting and establishing public infirmaries and hospitals and dispensaries in Ireland should be explained and amended:

"And whereas the vice-treasurer or treasurers of Ireland is or are empowered or directed, by an act of the parliament of Ireland of the fifth George Third, to pay a stated sum half-yearly to the treasurers of each infirmary or hospital in Ireland:

"And whereas it is enacted by an act of fifty-fourth George Third, that it shall and may be lawful for the grand jury of any county, county of a city, or county of a town in Ireland to present a certain sum as an addition to the salary of the surgeon or physician of the infirmary or hospital of such county, county of a city or county of a town, over and above the sum to

be advanced by the vice-treasurer or vice-treasurers aforesaid :

“ And whereas it is also provided by the aforesaid act, that before any such presentment shall be made, a certificate signed by at least five governors of such infirmary or hospital, as therein directed, shall be laid before the grand jury :

“ And whereas it is also provided by an act passed in the parliament of Ireland in the fifth of George Third, that the governor or governesses of any infirmary or hospital aforesaid shall at a general meeting appoint a standing committee to regulate the economy thereof ;

“ Be it therefore enacted, by the King's most excellent majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in this present parliament assembled, and by the authority of the same, That from and after the passing of this act no donor or donors of any sum or sums of money to any of the said infirmaries or hospitals shall be permitted to vote at any election, upon any vacancy which may hereafter occur for the office of surgeon or physician to such infirmary or hospital, unless he she or they shall have respectively paid the subscription by virtue of which he she or they claim a right to vote at such election, one year at least before such vacancy shall have occurred.

“ Be it further enacted, That all sum or sums of money directed to be issued by the vice-treasurer and vice-treasurers of Ireland, under the said recited act or acts, shall be applied either to the payment of a surgeon and a physician, or to the payment of a surgeon or a physician, except as excepted by the said act.

“ Be it further enacted, That the amount of any such presentment as is directed by the said recited act or acts shall be paid to the treasurer of such infirmary or hospital of such county, county of a city or county of a town ; and also that the certificate as directed by such recited act or acts aforesaid shall, in addition to what is

required by the said act or acts, contain the following words ; that is to say, ‘ that the said surgeon or physician hath since the late assizes diligently complied with the rules and regulations of the governors of the said infirmary or hospital ; and also that true copies of such letters testimonial as are required by the act of the parliament of Ireland of the thirtysixth George Third, to be obtained by such surgeon or physician, shall be laid before such grand jury previous to their making any such presentment.’

“ Be it further enacted, That in every case where the surgeon or physician of any infirmary or hospital is now required or enabled by law to receive any patient into the hospital or infirmary in his charge, other than by the written recommendation of one of the governors or governesses aforesaid, the said surgeon or physician is hereby required to report such case to the standing committee at the next meeting, as well as to preserve the certificates of all persons recommended on their admission ; and should any patient be so recommended by any governor or governess of any such infirmary or hospital, who on examination by such surgeon or physician, shall appear to him or them to be inadmissible, from the rules and regulations of the governors or governesses of any such infirmary or hospital, it shall be lawful for the said surgeon or physician to reject such patient as an intern patient ; and he is hereby required to explain, in writing, on the back of such certificate of recommendation, to such governor or governess so recommending every such patient, the due cause of his not admitting every such patient as aforesaid.

“ And be it further enacted, That no subscriber to any dispensary, for the support of which any grand jury in Ireland shall hereafter present any sum or sums of money, shall be entitled to vote at the election of any surgeon or physician of any dispensary as aforesaid, unless such per-

son shall have paid his or her subscription to the treasurer of such dispensary at least two years completed before any such election shall take place, save and except such persons as shall have subscribed to the said dispensary at its original formation, or prior to the first grand jury presentment in aid of the same.

"And be it further enacted, That every person who shall become an annual subscriber to any county infirmary, dispensary, or fever hospital, shall be bound to pay his or her subscription until the expiration of one year after such person shall have given notice in writing to the treasurer of such infirmary, dispensary, or fever hospital, of his or her intention to withdraw the same; and in default of payment thereof, it shall and may be lawful for the treasurer of such infirmary, dispensary, or fever hospital, to sue for and recover the amount of all arrears of such annual subscription in any of his majesty's courts of record in Dublin, if the amount shall exceed twenty pounds, and if under that sum, before the assistant barrister in the county in which such person or persons shall reside, and if in the county of Dublin, before the chairman of the sessions of Kilmainham, or if in the city of Dublin, before the recorder of the city of Dublin.

"And be it further enacted, That it shall and may be lawful to and for any grand jury in Ireland, at the assizes or presenting term next ensuing after the election of any such surgeon or physician as aforesaid, to call him before them, and to examine such surgeon or physician so elected, or any other person or persons in said county, upon oath, touching the said election; and if it shall appear that any offer, gift, promise, or loan of any money, or other valuable thing shall have been made, with the privity or on behalf of any such surgeon or physician, either then or in prospect, to procure any vote or votes for his election, it shall then be competent for the said grand jury, and the said

grand jury are hereby authorised and required, thereupon to withhold any sum or sums of money, presented or to be by them presented for or as the salary of the said surgeon or physician of such infirmary, hospital, or dispensary aforesaid; and then and in that case such surgeon or physician shall be deemed incapable of receiving at any future time any money by presentment from the said county, for the management of any infirmary, hospital, or dispensary within the same."

Rebieto.

Observations on Injuries and Diseases of the Rectum. By HERBERT MAYO, F. R. S., Surgeon to the Middlesex Hospital.

MR. MAYO is well known as one of the first physiologists of the present day, and his work, which we have now under notice, will give him the same rank in the surgical department of the profession. The anatomical structure of the rectum, its physiology, and the injuries and diseases affecting it, which admit of surgical relief, have formed a fruitful subject for writers of late, yet are we not the less disposed to value the rich store of information which we have gained from these works on that account. The volume before us contains "an account of cases intended to exemplify the principal varieties which are observed in diseases of the rectum, with the appropriate methods of treatment," and includes the following injuries and diseases, viz. fissure and laceration of the rectum; protrusion of the bowel; hæmorrhage and pain; piles; fistula; constipation; stricture and cancer of the rectum: and in the illustration of these Mr. Mayo has drawn largely from a variety of cases occurring in his private practice, for he remarks, that "diseases of the rectum are more common in the higher ranks of society than among the poor." Outward piles commonly appear in the following manner and run the following course:—

"After twenty-four or forty-eight hours, during which the patient has experienced ful-

ness, heat, and itching at the anus, a hard round lump, from the size of a pea to that of a chestnut, is felt on one side of the margin of the gut. It is extremely tender, so that the patient cannot bear to sit; and in every posture the pressure of the adjacent parts produces more or less aching pain. The patient finds relief sometimes from bathing the part with cold water, sometimes from hot fomentations and poultices, but more generally from the latter. Upon the use of one or other of these remedies, and a dose of laxative medicine, and rest and abstinence, the tenseness of the swelling and the sense of fulness and pain abate, and in forty-eight hours more so much amendment has taken place that the patient is able to sit and move about with comfort. The tumour, after a few days, shrinks entirely and disappears.

"The pain attending an attack of this description is of every degree, from inconvenience and discomfort, to intolerable suffering. The pain depends upon the fulness of the vessels of the part, and is often removed upon the occurrence of spontaneous bleeding from the mucous membrane of the bowel: it may always be mitigated by abstracting blood from the part by leeches. If the tumour is large the pain is generally greater, and, at all events, the swelling and induration are a longer period in subsiding."

We shall resume, next week, our notice of this work.

SPURZHEIM AND GALL.

A LITERARY journal (*The Athenæum*), has the following remarks on these phrenologists.

"The fact is, Spurzheim was an excessively uninteresting character, or rather he was a man of *no* character. He was a soft, easy, good-natured, and well-disposed man. We give him credit for believing what he taught, and following on with a sort of mill-horse sagacity the path that had been tracked out for him; but as far as there is any merit in the science it is all due to Gall. It was he who conceived the original idea, or we should more properly say revived it, as many rude attempts at mapping out the brain had been made before his time. It was he who attempted its extension and confirmation, by means of the most unwearied observations in prisons, schools, hospitals, mad-houses, in short every place where character was likely to be known or

developed. It was he who gave the first lectures on the subject, lectures of which Spurzheim was an auditor, and from which he derived the greater part of his knowledge. Finally it was he who first published those observations to the world in a connected form, for though the '*Anatomie et Physiologie du Système Nerveux*,' bears both names on the title-page, yet Dr. Elliotson says Gall assured him that every line of the four volumes was written by himself.

"Spurzheim's true merit, and that by which he will be known to posterity, depends on his accurate and faithful dissections of the brain. As an anatomist he might have shone. He had that untiring plodding disposition which, with a little mechanical dexterity, is the best qualification. He would scratch a little with his scalpel, look a little with his microscope, push a little with his thumbs, and then look again, until he had made out the minutest fibre, and unrolled the most intricate convolution.

"But the anatomical discoveries of Dr. Spurzheim, to which we are anxious to allow their full merit, have no manner of connection with his craniological opinions.

"Suppose we grant that the brain is the mind, in which case, of course, anatomical arguments would have most weight, how can we conclude that because the convolutions are separate, therefore they perform different functions, when we know that the liver of a monkey, or the kidney of a bird may be formed of many separate lobules, to which, however, no one ever thought of assigning different offices?

"This is a point on which we rather insist*, because it is generally put

* It is nevertheless a very weak one; we presume the reviewer to be ignorant of the circumstance that the liver and the kidneys have each their own *single* and appropriate function allotted to them, whereas the functions allotted to the brain are numerous and intricate, a fact which we have always thought tends to support many of the weakest arguments of the theory of Gall and Spurzheim.—
EDS.

forward as an argument to ignorant persons, why they should take the facts relating to the brain on trust, 'for surely Dr. Spurzheim must be correct there.' We think he is correct there, though we will not say how far his opinions are indebted to Riel's admirable papers published from year to year in the *Archiven für die Physiologie*, but allowing all this, it still remains to be shown how his facts bear on his theories."

Rather caustic, but yet correct in many particulars.

ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Allow me to correct some inaccuracies which occur in your report of a case at St. Bartholomew's, in your last week's Journal, and which you call a rupture of the urethra and laceration of the perineum. Now, the point of greatest interest in this case, consists in there being no external wound in the perineum from the injury. But as Mr. Stanley had no doubt of there being a rupture of the urethra, and thinking it probable that there was some infiltration of urine into the cellular tissue, as well from the great swelling, pain, and tenseness of the part, he deemed it advisable to make one, after evacuating the bladder by the catheter, the boy not having passed any urine for nearly twenty-four hours. In withdrawing the catheter, the end was protruded through the external opening in the perineum, proving the correctness of Mr. Stanley's diagnosis. The catheter has been kept in the bladder until within these few days, since which time the patient has passed his water by the natural passage. On another interesting point in this case, viz. the cause of the retention of urine, it was the opinion of Messrs. Stanley and Earle, that it arose from some improper action of the muscles of the bladder. Your accurate reporter

should have said that the scrotum was swollen and tense from effusion into its cellular tissue, and not that the testes were injured. As it is important that the reports of cases in a medical journal, should be correct, I do not apologise for thus intruding on you.

A PUPIL.

P. S. Permit me to acquaint you with an interesting result of the use of the tincture of iodine, ordered in the case of fungus of the testicle, reported also in last week's Journal, viz. that in about eight days the healthy testicle became evidently diminished in size, in consequence of which the medicine was discontinued, although the diseased testicle was improving under its use.

GENERAL DISPENSARY, ALDERSGATE-STREET. — RESIGNATION OF THE WHOLE OF THE MEDICAL OFFICERS.

At a meeting of the Governors of the General Dispensary, Aldersgate-street, took place on Wednesday, to take into consideration the proposition of the Committee—"To allow subscribers of three days' standing to vote at medical elections." This was opposed by the medical officers, who considered it injurious to the interests of the Institution, and to the respectability of the profession. The original motion was, however, carried, and thanks voted to the medical officers. Dr. Clutterbuck, Dr. Lambe, Dr. Birkbeck, Dr. Roberts, Mr. Salmon, and Mr. Coulson resigned, and announced that they would see their patients at their own houses.

Dr. Birkbeck read an extract from a letter addressed to him by his Royal Highness the Duke of Sussex, stating that in the event of the resignation of the medical officers, His Royal Highness would withdraw his name, as Patron to the Institution.

The Governors of the above-named Dispensary have often increased their funds, on former occasions, by tolerating a system of fictitious vote-

making, previous to medical elections. We believe they received, on one occasion, £500 from the supporters of one candidate, and, according to a correspondent, a like sum on other occasions. The medical officers, much to their credit, wished to put an end to this system of bribery, which evidently was injurious to the patients, as it enabled a man of wealth with slender medical attainments, to secure his election. It will be seen, in another page of this Number, that Parliament has put down this system of corruption at the medical elections in Ireland; and we have no doubt but it will be abolished in this part of the empire during the next session. We trust that there is not a physician or surgeon in London who will be so insensible to professional character as to sanction the bribery system of the Governors of the Aldersgate-street Dispensary, by disgracing himself in accepting office under them.

We could name another Charity, whose interests have been nearly destroyed by fictitious vote-making, contrary to the express wishes of its medical officers. We are satisfied that the time is at hand when the respect due to our profession will be duly estimated; and when interested tradesmen, clerks, and shopkeepers—men of narrow, ignorant minds—will, as governors, be divested of their insolence and impertinence to their superiors.

THE

London Medical & Surgical Journal

Saturday, September 14, 1833.

THE LEGISLATURE AND THE FACULTY.

WE congratulate our readers on the determination of the legislature to form one faculty of medicine and surgery, and to correct all existing abuses. The die is cast, and reform in all the medical corporations

must take place. We know, from authority which never deceived us, that numerous petitions and communications relating to personal injury, are daily pouring in upon Mr. Warburton and Mr. Hume. Applications are now being made to all the foreign universities and medical faculties, as regard education and the polity of the profession; and from the answers will be selected every feature worthy of adoption. The petition of the Licentiates against the College of Physicians astonished the committee of inquiry which sat upon the apothecaries' bill, and caused them unanimously to conclude, that while such abuses existed in the College, it would be impolitic to legislate for one branch of the profession until a general investigation into the whole faculty took place. The committee having thus concluded, it was a matter of course for the parliament to grant a committee of inquiry, of which the able, independent, and scientific Mr. Warburton will be the chairman. Happy for the profession, and more happy for the public, that a gentleman of such an enlightened mind, so much judgment, and such great influence with the legislature, will be the president of a court of inquiry, the results of whose labours will be of the greatest importance to humanity. Society is already indebted to this gentleman for the Anatomy Bill, that foundation of medical science, that fountain which supplies the limpid streams of a species of knowledge so important and beneficial to every rank in society, but

more especially to the poor and indigent. We are convinced that the philanthropic individual who proposed and carried that measure, will proceed in the great work of reform, secure to the public the blessings of health, and to the cultivators of the healing art, those rights and that encouragement which have been so long and so unjustly withheld from them, by the arrogant and illegal monopoly of those to whom the legislature and government intrusted the power of preserving the public health. We can most confidently assure our readers, that a complete reform will be effected in all our medical corporations, and that *religious tests* will no longer be suffered to exclude men of science and of eminence from places of rank and influence. Let the London and Dublin Colleges of Physicians digest this bitter truth as they can; the legislature prescribes it for their welfare. We are greatly amused at the commotion in all the corporations, and their liberal propositions of reform; but this shallow artifice is easily seen through; their fate is decided. We strongly urge our provincial brethren to meet and petition parliament against the present barbarous laws relating to the profession.

We take this opportunity of stating, that the reason the Licentiates' petition was not sent round to the physicians of London, was want of time, as it was suddenly got up on the eve of the adjournment of the committee on the apothecaries' bill.

DR. BAIRD AND HIS LIVERPOOL INQUISITORS.

WE perceive, by the *Liverpool Chronicle*, which reached us after our last number went to press, that the medical officers of the Manchester Infirmary, to whom the governors of the Liverpool Infirmary referred their charge of immorality against DR. BAIRD, have unanimously resolved "that no imputation rests upon the moral character of Dr. Baird for his conduct on this occasion."—Signed Edward Lyon, M.D., James Lomas Bardsley, M.D., J. Davenport Hulme, M.D., J. A. Ransome, Rich. Thorpe, W. James Wilson, Thomas Turner. We always anticipated this decision from such eminent physicians and surgeons as the medical officers of the Manchester Infirmary. But we felt convinced that such a decision would make no impression on the base calumniators of Dr. Baird. We were quite right. At a meeting of the Governors it was resolved, after reading the above, "it is the opinion of this meeting that no farther proceedings are necessary." We cannot comment upon this conclusion without reiterating our former conviction, that there are some influential but unprincipled knaves connected with this outrageous transaction. Did ever the world hear of such a proceeding, as to blight the character of a physician, to ruin, to beggar him, by trumping up an unfounded charge of immorality against him, and when he is acquitted the libellers think farther proceedings unnecessary. Even an expression of regret does not escape, much less a

vote of thanks. Were we concerned with these worthies, we should meet in the King's Bench, and show them that the reputation of a physician must not be unjustly injured with impunity. Dr. Baird may fear further publicity, but he might rest assured, that the whole profession in this metropolis would carry him triumphant in the same manner as their brethren in Manchester.

THE ANATOMY BILL.

WE have had an interview with the inspector of anatomy, and have much pleasure in stating, that the charge of partiality urged against him is unjust and unfounded. We have perused all the documents for and against it, and are bound to declare, that no blame whatever is due to him. If those applying to him refuse to comply with the terms he has entered into with parishes for the supply of unclaimed bodies, terms approved of by nearly all the anatomical teachers in this capital, they must blame themselves.

THE CHOLERA.—THE PUBLIC PRESS.

THIS formidable disease has nearly disappeared. We regret to notice the unjust and unmerited censures of an influential part of the public press, on the conduct of the medical profession in respect to cholera. It is maintained that medical men did not investigate the disease or endeavour to combat it. Never was there an accusation so unjust or so groundless. The truth is, that there is not a powerful remedy in any pharma-

copœia in the world which has not been repeatedly tried, and every effort made that science justified.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Laceration of the Scalp, and Fracture of the olecranon and inner condyle of the arm.—H. Ward was conveyed into the hospital on Friday Sept. 6th, having just met with the following accident. While asleep on the side of his cart, the shaft suddenly broke, and he was thrown with great violence on the ground. The wheel of the cart went over the right side of his head, and he was immediately brought to the hospital, when, upon his admission, he was bled to between thirty and forty ounces. Mr. Earle examined him, and found the scalp and temporal muscles of the right side of the head dreadfully lacerated; the bone was not fractured. Mr. Earle then dressed the wound; he removed with the knife some of the scalp and muscle, which, from the violence done to them, had lost their vitality. On further examination, it appeared that considerable injury had been done to the elbow-joint. The olecranon was fractured in two places, and also the inner condyle. The patient, on recovering from his state of insensibility, obstinately demanded to be let go home, but Mr. Earle entirely disapproved of such a step, and remonstrated with him on the rashness of leaving the hospital while in such imminent danger; the man, however, was determined on going, but was prevented by his suddenly falling into violent convulsions.

In reference to this case, Mr. Earle remarked in his clinical lecture of Saturday Sept. 7th.—“This, gentlemen, is a most interesting case, and I recommend you all to mark well its progress, and the treatment pursued by us. Now if the patient happens to survive this accident, we are to consider what is to be done with the

elbow-joint, which you know is severely injured; and in this we are to consider what position the arm should be kept in, whether in the flexed or straight position. I am decidedly of opinion, that the flexed position is the better, for when a patient, in such case, has an ankylosed elbow-joint, there can be no doubt of the flexed being the best position, as he can then feed himself, wash himself, and perform several other necessary duties which a man with an ankylosed elbow-joint, in the straight position, cannot do; indeed it is impossible to conceive a more helpless condition than that of a man with an ankylosed joint in a straight position. With regard to the injury done to the head we are to expect many results; from the great violence done to the scalp and bone, I think erysipelas will be a very probable consequence. This we must guard against. We may also expect considerable exfoliation of bone."

ST. GEORGE'S HOSPITAL.

Rupture of the Spleen.—A labouring bricklayer was conveyed into the hospital on the 27th August, in a state of insensibility, having just fallen from a height of fifty feet. His pulse was very small, and his pupils were very much dilated, respiration difficult and stertorous. He was bled shortly after admission, but remained insensible till 2nd Sept. when he died. On a post-mortem examination, the spleen was found to be ruptured, and all the abdominal viscera bore the marks of contusion. A great quantity of blood was found in the cerebrum.

Femoral Aneurism—Operation by Mr. Hawkins.—*Double femoral artery on one side.*—Samuel Broadbrim, a stout athletic labourer, æt. 24, was admitted into the hospital on the 28th August with femoral aneurism of the left limb. About six months ago, while in the act of making a violent strain to grasp at some object, he felt a sudden twitching pain in the part where the aneurism exists; some time

after the thigh swelled and became painful, which prevented him from following his occupation, and obliged him to seek admission into the hospital. On examination we found the aneurism situated about the lower part of the femoral artery, two or three inches above the knee-joint; the limb was slightly cedematous. On pressing the femoral artery high up, near Poupart's ligament, the aneurismal tumour abated, and became even with the other parts of the thigh. On removing the pressure the tumour again enlarged, leaving no doubt of its being purely aneurismal. No other resource being left, Mr. Hawkins proposed to tie the femoral artery, which he did accordingly on Thursday 5th Sept. The artery was taken up within three inches of Poupart's ligament. Mr. H. having made a longitudinal incision through the muscles carefully dissected away the fat, and, having discovered the artery, he passed the ligature round it. The patient was then removed to bed; aperients were administered, and he is now doing as well as could be expected.

Mr. Hawkins, among other cursory remarks, which he made after the operation, said that he recollected a case in the Middlesex Hospital some years ago, in which two femoral arteries were found. The patient was in the hospital for femoral aneurism. The operation was performed, and the femoral artery taken up, but the patient died shortly after, the aneurismal tumour being supplied by the other femoral artery, which running under the one which had been tied, escaped observation and remained untied.

Excision of Tumour from the Cheek.—On Thursday, September 5, Mr. Walker performed excision of an indurated tumour of the cheek in Elizabeth Hedhes, a young woman, ætat. 20. The tumour was of some months' standing, and was deeply rooted. Mr. W. having made an incision through the integuments and

muscles, dissected out the tumour; one artery was tied. On examining the tumour, after the operation, it appeared glandular in its structure, less organised, however, than glands in general are. The operation lasted fifteen minutes, and was borne by the patient with great fortitude.

Stricture of the Œsophagus.—Jediah Cooper, a middle-aged woman of very unhealthy appearance, came to the hospital the other day complaining of perfect inability to swallow solids during the last eight months. Even the deglutition of fluids was accompanied with difficulty. Her general health has been much impaired, and looks are strongly expressive of anguish and pain. Mr. Babington passed a bougie down the pharynx, with a view to ascertain the exact seat of the stricture. The stricture exists at the termination of the pharynx in the œsophagus. A few days after the first introduction of the bougie, Mr. Babington passed another, the extremity of which was armed with lint, immersed in the solution of nitrate of silver. Mr. B. said, that in cases of stricture of the œsophagus, occasioned by a thickening of the surrounding coats, very little relief can be afforded by any measures. No change for the better has yet taken place in this woman, for whom Mr. Babington continues to introduce the bougie two or three times a week.

Stricture of the Rectum.—There is a case of stricture of the rectum at present in the hospital. The patient is a young woman, about thirty years of age. The stricture has existed from her infancy. Bougies are constantly introduced and allowed to remain in the intestine for some time.

The case of secondary hæmorrhage after amputation, mentioned in our last, in which it was found necessary to take up the femoral artery, is now going on well. No disposition to bleed has been discovered in the stump, and the patient is comfortable

in every respect. His bowels have been kept well opened, and he sleeps well at night. The stump presents a healthy appearance.

MIDDLESEX HOSPITAL.

Ligature of the External Iliac Artery.—Dyer, ætat 34, was admitted into the Middlesex hospital under the care of Mr. Mayo, Sept. 4th. Five weeks previously he observed a swelling of the size of a walnut situated above the middle and upon the inner and fore-part of the thigh. The tumour was painful, and the pain extended down to the inside of the knee. A fortnight after its appearance he was driving an open cart, the jolting of which increased the pain in the tumour considerably, and it enlarged rapidly in size.

At the period of his admission, the tumour was of great size, it was elevated about three inches at the centre above the surrounding skin, and had at its base a diameter of five inches. This, however, could not be so accurately circumscribed or defined; the mass of the tumour was moveable from side to side. The patient was very tall, and corpulent for his age. He suffered continued aching pain in the tumour, and over the inner surface of the knee and leg, and the instep was numbed from the pressure of the swelling on the saphenus nerve. The tumour was hard and firm, and could be seen to rise synchronously with each pulsation of the wrist. When the hand was laid upon it, the impulse was felt to be equal over every part of the surface, and the *bruit de soufflet* was distinctly audible.

The patient's countenance expressed distress, and the pulse was hard and frequent; he was bled with some slight diminution of pain. It was determined to tie the artery on the following Monday after his admission, after being kept perfectly quiet for a few days, and placed upon proper diet and medicine. Upon visiting the

patient on Sunday morning, Mr. Mayo found him much worse; the tumour had much enlarged, it was more painful, and he had slightly wandered in the night. A consultation was held, and by the advice of his colleagues, Mr. Mayo decided upon performing the operation, which was done at 3 P.M. The ligature was placed upon the external iliac, as the aneurismal swelling extended nearly as high as Poupart's ligament, and left not sufficient space for a ligature to be applied on the femoral artery.

One hour after the operation, the pain of the tumour had subsided, and the numbness of the leg and knee was considerably lessened. The limb had its natural warmth, but those who saw the patient augured ill of his recovery, from his anxious countenance and gross habit of body.

*R Pulv. ipecac. comp. gr. v.
Hydrarg. submurial. gr. iij. M. Fiat
pulvis hac nocte sumend.
Haustus aperiens cras primo mane.*

On visiting him the following morning, it was reported that he had but little sleep in the night; the bowels had been relieved, and the patient expressed himself better, and freer from pain; the tongue was dry and slightly furred, and the pulse was feeble, frequent, irregular, and unequal. He complained of constant thirst, and was allowed soup in the course of the day and cold tea. As there was some tenderness over the lower part of the abdomen, twelve leeches were applied, and fomentations. At 10 P.M. he appeared much worse; pulse 120, feeble and irregular; breathing hurried; tongue dry, and considerable delirium. Mr. Mayo ordered him

Pulv. ipecac. c. ℞j. statim sumend.

Prognosis of the case highly unfavourable.

10th. On visiting him this afternoon (forty-eight hours after the operation), a very favourable change was found to have occurred in his symptoms. He had slept well; tongue

was moist, system tranquil; no restlessness and delirium. There is slight tenderness around the wound; tumour diminished one-third in size; discoloration and pain quite gone.

EDINBURGH SURGICAL HOSPITAL.

Double Hare Lip in an adult remedied by one operation.—Norman Robinson, ætat. 17. In this case there was no malformation of the jaws or palate, and the portion of lip which lay between the two fissures, though it presented a nipple-like appearance being of a triangular form and shorter extent than the parts on each side, was natural in its consistence and connexions. The respective edges having been rendered raw by removing a slice from each by means of a sharp pointed knife, a needle was passed through them, so as to transfix the apex of the intermediate portion, which was about midway between the nose and edge of the lip. Two other needles were then introduced, one being close to the *prolabium*, and the other at the margin of the nostrils. The edges of the wounds were brought into exact contact by threads applied round the needles. They united completely by the first intention, and the patient was dismissed greatly improved in appearance.

Single Hare Lip in an adult.—John Scott, ætat. 21. In this case there was a fissure of the palate throughout its whole extent, and considerable irregularity of the adjoining edges of the alveolar process. The operation had been performed when he was two years of age, but failed, owing to his restlessness afterwards. One of the incisors which projected between the edges of the fissure having been removed, the corresponding surfaces were prepared for union in the usual way with the knife, which was rather difficult, in consequence of the induration of the cicatrices that had resulted from the

former attempt. A needle was introduced close to the margin of the lip, and two stitches of the interrupted suture were employed to draw the remaining portion of the edges together, as the latter means seem less apt to occasion troublesome ulceration than the twisted suture, when the parts to be joined are put upon the stretch. The cure was completed without any unfavourable occurrence, and the patient returned home well.

Hare Lip in a Child—Malformation of the Jaw—Operation postponed.—Grace Crerar, ætat. 2. This was one of those cases in which the central part of the superior maxillary bone is produced into a round knob, having the corresponding portion of lip attached to its anterior surface, and to the *columna nasi*, in the form of another similar but smaller knob. Behind this projection there was a very broad fissure, or rather deficiency of the palate throughout its whole extent. As the intermediate portion of lip could not be rendered serviceable, owing to its situation and connexion, it was removed, together with the malformed portion of the jaw, and the cheeks were then drawn together by means of adhesive plaster, so as to prepare them for permitting the edges of the lip to be united. After a careful trial of this plan for several weeks, it appeared that no material advantage had been obtained, the child being so strong and unruly as to render it impossible even with the hands to retain the sides of the fissure in approximation, and it was therefore judged prudent to delay making any attempt to effect adhesion until the child acquired more docility, and until the two halves of the jaw became closer, as they might be expected to do in the course of time after the removal of the central portion.—*Edin. Med. and Surg. Journ.*

French Hospital Reports.

HÔPITAL DES VENERIENS.

(Original Report.)

Remarks on Tonsillar, Sublingual, and Anal Ulcers.

BY ALEX. THOMSON, M.B. OF ST. JOHN'S CAMB.

(Continued from p. 27.)

Ulcers of the anterior Palatine Pillars, their progress.—From the 3rd to the 13th of April unchanged.

13th. The anterior palatine pillars have each, about the middle of their oral portion, an oblong regularly margined ulcer, with the long diameter parallel to their own free margin, with abrupt, red, hard edges, and a uniform yellowish-grey bottom, resembling chancres, and having each one quarter of an inch in vertical, by one-sixth in antero-posterior diameter.

From the 14th to the 16th unchanged.

17th. The only parts of the throat now red are the anterior palatine pillars, the ulcer of the right of which is doubled in magnitude, and occupies its free edge as well as its anterior face.

From the 18th to the 20th unchanged.

21st. The ulcer of the right anterior pillar of the soft palate is completely cicatrised, with a thin epiderm, generally redder, and a little more elevated than the face of the pillar itself, but without contraction or puckering of the surface. That of the left palatine pillar has ceased to be hollow, has its edges less red, and sunk nearly to a level with the face of the pillar; is irregularly round in form, one quarter of an inch in diameter, and covered on its surface with a whitish slough.

22nd. Unchanged.

23rd. The cicatrix of the right palatine pillar is again opened, and nearly covered with a whitish slough: the ulcer of the left palatine pillar is considerably diminished, level with the surfaces, and unsurrounded with redness.

24th. Unchanged.

25th. The right palatine pillar ulcer is again perfectly cicatrised and on a level with the surface of the pillar, the cicatrix being flat, but redder than the surrounding parts. The left palatine pillar ulcer very nearly cicatrised, on a level with the pillar surface, having scattered upon it two or three spots of the size of a linseed, and whitish, the cicatrising membrane being a little redder than the surrounding parts.

26th. The left palatine pillar ulcer all cicatrised, with the exception of a small spot about the size of a linseed, with a smooth, unswollen, flat, bluish-red cicatrix.

27th. Both anterior palatine pillars less red, the cicatrix of the right being now untraceable. The ulcer of the left is now also perfectly cicatrised, with an uncontracted, unpuckered, unelevated, bluish-red cicatrix, yet paler than the surrounding parts.

28th. The left palatine pillar cicatrix also of the same hue with the surrounding parts, but having in its middle two small, round, flat, thin, whitish-yellow spots, each one-third of a line in diameter, resembling little sloughs.

29th. Unchanged. 30th. Not seen.

31st. The yellow spot-like sloughs on the left anterior palatine pillar have fallen, and are replaced by cicatrices similar to those already described.

June 1st. Cured.

Remarks on the nature, progress, and cure of these Palatine Pillar Ulcers.—These ulcers it appears commenced at the same time with those of the tonsils, had all the external characters of chancres except the hardened base, but were not tested by inoculation; were regarded by M. Ricard as secondary ulcers. They were remarkable for the symmetry of their position, the uniformity of their characters, the unequal effects of the treatment on them, for their first cicatrices in both cases re-sloughing, and being speedily re-cicatrised, and for both terminating, without contraction,

in flat, even, unelevated, unpuckered cicatrices, speedily resuming the hue of the surrounding parts.

Both of them had lasted, without improvement, for ten days before I saw them, and continued subsequently without any very decided change in aspect for four days more, when, on the fifth, that is, the fifteenth after his application to M. Ricard, the right was doubled in magnitude. Repose in bed, half nourishment, barley-water drink, simple and opiated marsh-mallow gargles, and one gentle hot bath of an hour's duration, had therefore had no influence on them. On the fifteenth day the use of the protioduret was commenced. The right ulcer was perfectly and finally cicatrised, and the left all but in that state, the day before the mouth became sore, this rapid improvement having taken place during the four days, in which the pulse was reduced to 66. The further progress of the left ulcer appears to have been slower after the affection of the mouth. Four grains were taken in successive days with the sarsaparilla drink, without any change whatever supervening, when the right ulcer became suddenly cicatrised after the fourth pill in the space of twenty-four hours, while, on the same day, the left had closely approached towards cicatrification. The right re-sloughed again after the eighth pill, and was again cicatrised after the seventeenth. The left cicatrised after the tenth pill, re-sloughed over scattered spots on the eleventh, and again cicatrised after the fifteenth pill.

HÔTEL DIEU.

Anomalous nervous affection—Barking caused by a convulsive state of the larynx—Cure.—A boy of a weak and delicate constitution, aged 10 years was admitted into the Hotel Dieu. Six months since (without being able to assign any appreciable cause for it) he was seized with nausea and a desire to vomit without ever having been previously affected

in a similar manner. From this period he became almost constantly subject to a spasm or convulsion of the larynx. He had at first a difficulty in pronouncing words and then in articulating them. His disease appeared to M. Dupuytren to consist chiefly in an alteration of the vital properties of the laryngeal muscles which were no longer under the controul of the will. The movements of the larynx were very great and rapid, it rose and fell half an inch with such constant rapidity, that it was difficult to follow its motions. It therefore necessarily resulted that the windpipe was alternately shortened and lengthened, and from this irregular contraction and relaxation of muscles, those destined to stretch or to narrow the vocal chords over the opening into the glottis being affected by spasm, produced sounds more or less full or sharp. The voice was likewise vitiated, and resembled that of an animal, more nearly that of a dog. Infusion of valerian and pills of meglin were ordered; one dose only of these was taken, and on the following morning the boy spoke with ease and freedom.

LITERARY INTELLIGENCE.

DR. UWINS is preparing a new edition of his valuable Treatise on Indigestion and Nervous Complaints.

BOOKS.

Nature and Treatment of the Epidemic Cholera. By ROBERT VENABLES, M.D. 2nd edit. pp. 52.

Report on the Alterations necessary in the Act of 1791, made to the General Council of Apothecaries' Hall by the Parliamentary Committee. Pp. 11. Dublin.

Enchiridion; or a Hand for the One-handed. By G. W. DERENZY, Capt. H. P. 82nd regt. 8vo. pp. 60. Several woodcuts.

The design of the author of this work is to propose a number of contrivances for the one-handed, which show great ingenuity of invention. This little book deserves to be known to all surgeons in large cities and manufacturing towns, but especially to those of the army and navy.

Encyclographie des Sciences Médicales. Reimpression Générale des Ouvrages Péri-

diques sur ces Sciences, publiés en France, savoir :—Cours de Pathologie et de Thérapeutique Générales, de Broussais; Annales de la Médecine Physiologique, de Broussais; Bibliothèque Homœopathique; Archives Générales de Médecine; Revue Médicale Française et Etrangère; Transactions Médicales; Journal Universel et Hebdomadaire de Médecine et de Chirurgie Pratiques, etc.; Journal de Médecine et de Chirurgie Pratiques; Gazette Médicale; Lancette Française, Gazette des Hôpitaux; Annales de Hygiène Publique et de Médecine Légale; Bulletin Général de Thérapeutique Médicale et Chirurgicale; Journal de Pharmacie et des Sciences Accessoirs; Journal de Chimie Médicale, de Pharmacie et de Toxicologie; Brochures, Mémoires, Thèses, etc.

The object of this work is to re-print in Belgium all the medical periodicals of France, and at so low a price, as to render the whole accessible to all persons engaged in the study of the medical, surgical, or pharmaceutical sciences. A volume, containing 300 pages, royal octavo, is published every month, at the moderate price of six shillings, while all the French periodicals it contains would amount to twenty pounds a year. Nine volumes have already appeared of this work. Those who are interested in the progress of foreign medicine, will find this work the most comprehensive and cheapest hitherto published.

A Synopsis of Systematic Botany, as connected with the Plants admitted into the pharmacopœias of London, Edinburgh, and Dublin; accompanied by a Planisphere, showing at one view the class and order of the medical genera, according to Linnæus and Jussieu. By THOMAS CASTLE, F.L.S. of Trinity College Cambridge, Member of the Royal College of Surgeons, London, &c. &c. pp. 17, 4to. E. Cox, New-court, Southwark, 1833.

A useful work for students.

CORRESPONDENTS.

Dr. Bardsley shall hear from us by letter.

Riverius.—Two six months' courses are sufficient, provided our correspondent be of age. Candidates cannot appear at the Hall until 21, or at the College until 22.

King's College.—We shall have much pleasure in inserting the article in our next.

Philo's communication is received.

We have to acknowledge the receipt of the following newspapers; The Liverpool Chronicle, The Scotsman, The Dublin Weekly Freeman's Journal, The Morning Register, The Caledonian Mercury, and the Hampshire Telegraph.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

No. 86.

SATURDAY, SEPTEMBER 21, 1833.

VOL. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE I.V., DELIVERED FEB. 20, 1833.

GENTLEMEN,—In continuing the subject of aneurisms, the next circumstance to which it is necessary to call your attention is, that when the aneurism is of some size, the sac always acquires an intimate adhesion to the neighbouring parts. On this account, after the three coats of the artery have given way, and even after the sheath of the vessel has been absorbed, the blood does not in all cases become widely diffused, but is still confined within certain limits by the adhesive inflammation. Then the new part of the sac, of whatever soft texture it may be composed, increases gradually, like the rest of it. However, in certain examples, the sac bursts, or is lacerated so suddenly, that no time is afforded for the adhesive inflammation to produce the desirable connexion of parts, and then the blood is apt to be diffused through the cellular membrane. The tumour of course undergoes a sudden enlargement, and spreads itself over a greater space; this case is sometimes called by surgeons a *secondary false aneurism*, because the disease changes from the circumscribed to the diffused state, in consequence of the rupture of some part of the sac.

With respect to the symptoms of aneurism, I scarcely need inform you, gentlemen, that there must be a difference in them according to the *situation* of the tumour, and according as the aneurism may happen to be an internal or an external one. At present I will confine my observations to the symptoms of a true aneurism in an external situation, that is to say, an aneurism that is out of the boundaries of the abdomen and chest. Such an aneurism, as usually seen on one of the limbs, generally begins in the form of a small pulsating tumour,

which subsides on pressure, but, on the pressure being removed, the swelling immediately returns. While the aneurism is small, the blood which it contains may thus be forced out of it by pressure, but it returns into the aneurismal cavity as soon as the pressure is discontinued. You will also remark a diminution of the prominence and tension of the tumour, when the artery leading to it is compressed. The same circumstance causes the tumour to beat more feebly, and sometimes stops the pulsation altogether; but, as soon as this kind of compression is removed from the artery, the tumour becomes as full and tense as ever, and beats with its usual force. These are strong circumstances, which leave no possibility of mistake. While the tumour is of diminutive size, it does not cause much pain, or inconvenience; but when, from its increased dimensions, it begins to make a good deal of pressure on the neighbouring parts, and especially on any nervous trunk in the vicinity of it, then the patient complains of severe suffering. In the early stage, while the aneurism is small, and the sac contains no lamellated blood, the tumour beats distinctly and forcibly, the blood in it being entirely fluid; in a more advanced stage, as the tumour enlarges, a portion of the blood in it becomes solid, and cannot be completely pressed out, and not only does it assume a concrete state upon the inner surface of the sac, but the sac itself, and the adjacent cellular membrane become thickened. The cause then of the impossibility of completely emptying the tumour any longer by compression, and of the reduced force of its pulsations is manifest. Now also, in consequence of the pressure on the neighbouring parts, the disease begins to give severe pain, and from the same cause, the circulation begins to be seriously obstructed, the adjoining veins and lymphatics being included in the parts suffering from the pressure of the aneurismal tumour. The pulsation, however, though not now so strong as in the early stage, is still distinct. But in a more advanced stage, the size and solidity of the aneurism are yet more increased, and the pulsation of the tumour may become so weak as to be perceptible only at the point immediately opposite the communi-

cation of the artery with the aneurismal cavity. In fact the sac is sometimes almost full of solid fibrine, and the proportion of fluid blood in it is but small.

Now, gentlemen, there are two circumstances deserving your particular attention in considering whether a case be aneurism, or not. First, you must not regard the pulsation of a tumour as a certain proof that the disease is aneurism; secondly, you should not assume, as a matter of certainty, that the disease is not aneurism because it happens to present no pulsation. In the beginning of these lectures I mentioned a case which I visited at Egham in Surry, with Dr. Smith and Mr. Baker of Staines, and Mr. Gilbertson, of Egham; it was that of a young man, who had a prodigious swelling extending over a considerable part of the abdomen, especially the epigastric region, and attended with as strong a pulsation as that of the aorta. The question was, whether the disease was an aneurism? and as one portion of the tumour was on the point of bursting, the patient was in rather a critical situation. Now, though this tumour pulsated so forcibly, it was not an aneurism, and we arrived at that conclusion from the consideration of two or three circumstances. In the first place, it was inferred, that, with an aneurism of that size, the patient would have experienced more suffering than he did; the functions of the viscera, and especially of the stomach, and the action of the diaphragm would also have been interfered with in a dangerous degree, whereas this was not the case. These circumstances were decidedly in favour of the case not being an aneurism; then in the course of my inquiries, I happened to learn, that the patient, when a boy, had had disease of the hip-joint, which gave us an insight into the nature of his constitution; for the form of disease of the hip to which I allude, chiefly attacks persons of a scrofulous habit, and it is known that chronic abscesses of a large size are particularly disposed to form in individuals of the same kind of constitution. In fact this was the most complete example of chronic abscess I ever saw, for the patient made no complaint, till three or four days before I saw him, and had been able to follow his usual employ, and if I remember rightly, to attend the races in the neighbourhood. Thus you may conceive what an indolent description of abscess it must have been. A day or two after I saw this patient, the tumour burst, and a gallon or two of pus was discharged. The lad recovered. In the Blue-coat school, many years ago, I saw a case very similar to what has now been described; the gentleman with whom I served my time, was surgeon to Christ's Hospital, where one of the scholars had an abscess extending from the ribs to the back of the pelvis; the tumour throbbed as regularly and forcibly as the aorta itself, yet from a variety of circumstances, Mr. Ramsden was convinced the disease was not an aneurism, and he punctured the swelling; the result was an immense discharge of mat-

ter. Such facts teach you to be upon your guard, and not to consider pulsation as the sure proof of the existence of aneurism.

Some pulsating tumours may be distinguished from aneurisms by the circumstance, that, in the former, the pulsation is rather a change of place of the whole swelling, than the kind of motion arising from the injection of a fluid into its cavity; it is, in fact, a sort of displacement, occasioned by the impulse of the blood through a neighbouring large artery. However, in certain cases, it may be difficult to say, whether the motion is produced by the former or the latter of these two circumstances; the two abscesses, to which I have referred, could not have been so distinguished. There is another better plan, I think, of forming a judgment in ambiguous cases; when a tumour pulsates, in consequence of its being situated over a large artery, you may sometimes be able to lift it off the artery, or move it to one side, so as to place it out of the influence of the vessel, and then it will be evident that the beating does not depend on the injection of blood into the subjacent artery, for the pulsation of the tumour, thus removed a little way from the vessel, will be observed to cease. This is an useful fact to recollect, for, in some situations, very correct information may be gained by the mode of proceeding which I have described. But, gentlemen, one valuable source of information, in doubtful cases, is the stethoscope, or mere auscultation when that instrument is not at hand; for, by these means, if the disease be an aneurism, you may distinguish a *bellows-sound*, a noise within the tumour, usually compared to that of a pair of bellows at work. Having apprised you, gentlemen, that it is not every pulsating tumour which is an aneurism, let me now bring under your notice another fact, namely, that a swelling may be an aneurism, though it does not pulsate. When an aneurism suddenly changes from the circumscribed to the diffused state, there is generally a diminution of the force of the pulsation, and sometimes the beating entirely subsides. At first, when the blood escapes into the cellular membrane, so as to become extensively diffused through that tissue, the pulsation either becomes imperceptible or feeble, and, after a time, it ceases altogether. The same thing sometimes happens when aneurism has advanced beyond a certain stage, even though not diffused; thus, when its cavity is filled with lamellated blood, by which it is converted into a solid swelling, the jets of blood no longer pass into it, but for some time before the cavity of the aneurism is entirely blocked up in this manner, the pulsation is obscure, and at length it is completely lost. I once saw an aneurism of the popliteal artery, where, with the concurrence of several professional men, amputation was performed, on the supposition that the tumour was of a different nature, involving the bones of the knee-joint. Now this case was, as I have said, a popliteal aneurism, and

the disease had made considerable progress to a spontaneous cure. The swelling, which was remarkably hard, reached far over the side of the joint, and, according to the patient's account, had never pulsated; these circumstances, joined with the imperfect history given of the case, led to the conclusion, that it was not an aneurismal tumour. Before amputation was commenced, a lancet was thrust into the tumour, but the slight hæmorrhage, which followed the experiment, only tended to confirm the idea of the case not being an aneurism. The limb was therefore removed, after which the dissection made the true state of things clear enough; the disease was found to be an aneurism, the cavity of which had been filled with solid lamellated blood, so that the most essential preparation for a spontaneous cure had been made by nature.

Now, gentlemen, when the case is one of *diffused false aneurism*, the pulsation is generally feeble and indistinct, the limb is cold, and, in consequence of the extensive injection of blood into the cellular membrane, you may remark, that the skin is more discoloured than in true aneurism, unattended with inflammation; and you will see an appearance very like that of ecchymosis. When such an aneurism is the consequence of the bursting of a true aneurism under the skin, and this sometimes in rather a deep situation, the disease universally receives the name of a *secondary false aneurism*. At the moment when the change from the circumscribed to the diffused state happens, the patient is generally conscious of a sudden snapping, or breaking of something in the limb. The tumour immediately undergoes a remarkable increase of size and change of shape, and spreads over a great extent of the limb. Directly after these events, a sudden diminution of the force of the pulsations is noticed, and sometimes even a total stoppage of them, generally the beating is very suddenly reduced, but still continues in a feeble manner for a few days, and then ceases altogether. In the summer before last, I had a patient, on whom I was going to perform the operation for popliteal aneurism, but in consequence of his being attacked with gout, this proceeding was necessarily delayed. As the tumour was exceedingly large, I explained to the patient, at my first visit, and before his gout came on, that any delay of the requisite operation would be accompanied by a risk of the swelling giving way; but, as I have said, his attack of gout rendered it necessary to encounter the danger. In about a week, the aneurism really gave way. This happened at a period when the whole limb was enormously swollen and cedematous, the leg being as thick as the body of a person of ordinary stature. The sac gave way also in a deep situation, close behind the head of the tibia. A prodigious extravasation of blood immediately followed, a part of it being propelled even down to the heel; but, on account of the previously cedematous state of the limb, the dif-

fusion of blood in the cellular membrane did not produce much change in its shape, or in that of the tumour. However the pulsations underwent a sudden reduction, and the limb became all at once remarkably cold. The question now was, whether the lessening of the force of the pulsations was owing to the tumour being filled with lamellated blood, or to the rupture of the sac, and the change of the aneurism from the circumscribed into the diffused state? By means of auscultation Mr. Lawrence, who met me in consultation, ascertained most decidedly, that the jets of blood were still passing into the sac, and this circumstance threw considerable light on the case. However, as the temperature of the limb seemed higher than it was in the morning, I was led to recommend postponing the operation for aneurism a little while. However, urgent symptoms of gangrene coming on, I afterwards tied the femoral artery, but such was the effect of the distension and injection of the cellular tissue with blood, that the operation answered no purpose, and it became necessary to amputate the limb. This was done, and the patient recovered. In this case I amputated of course before the red line of separation had formed, and if I had waited six hours longer than I did, the patient would have been inevitably lost.

Then, gentlemen, you are to regard, as symptoms of the change of a true into a secondary false aneurism, the following circumstances:—a diminution, a sudden cessation of the pulsation in the swelling; a change in the shape of the tumour; a sudden extension of it over a greater part of the limb; a sudden diminution of the temperature of the limb, and a degree of discoloration of the skin; a kind of ecchymosis. If you should happen to meet with a case, where you could not immediately say whether the change in the circumstances and condition of the tumour and limb were owing to the bursting of the sac, or to the pressure of the tumour and its becoming filled with lamellated blood, you should use the stethoscope, which will give you positive information whether the jets of blood into the sac are still continued or not.

Gentlemen, the next fact to which I invite your attention, is, that the solid blood, or fibrine, in an aneurismal sac, is always deposited in concentric layers, which are invariably noticed to be particularly firm on the side, towards the interior surface of the sac. Here, too, they are also paler than they are more towards the centre of the aneurism, presenting an appearance very much like that of boiled meat. No doubt some of the coagulated blood, which is found in the aneurismal sac after death, is deposited there subsequently to that event; but you will find the true lamellated blood always more firm and pale the nearer it is to the parietes of the sac. Here is a large aneurism of the aorta, with lamellated blood in the sac, arranged in concentric layers. The outermost layer, you will

find, is always closely attached to the cyst, and sometimes so adherent to it, as to be almost inseparable. This deposition of fibrine, or lamellated blood, seems to be designed as a means of strengthening the sac, and as a protection against hæmorrhage; nature appears to arrange this solid substance, however, not merely as a barrier against hæmorrhage, but as a means of occasionally bringing about a cure of the disease. The deposition of lamellated blood in the aneurism generally commences at an early stage of the disease, and sometimes goes on gradually to such an extent, that the sac is completely filled up, and then the tumour, instead of consisting chiefly of fluid blood, is altogether solid, is afterwards absorbed by degrees, and what is termed a *spontaneous cure* follows.

I have explained to you, that the layers of lamellated fibrine differ in appearance according to their date; the most central ones, or those which are furthest from the sac, consisting simply of blood, more or less firmly coagulated; a little further outwards, or more towards the sac, they are paler, and evidently composed of a large quantity of fibrine, and still further outwards, they are exceedingly firm, quite pale, and very like boiled meat. I have seen some specimens, which could hardly be distinguished from boiled beef, except by the arrangement of their concentric layers. Those strata which have been recently deposited, adhere together but slightly, but the others are intimately connected. The deposition takes place more quickly in false than true aneurisms, and the reason of this fact is, that after the coats of the artery have given way or ulcerated through, the communication between the artery and the sac is not so free and wide as previously, the blood in the tumour, therefore, is retarded in its course, and this circumstance, we know, always promotes its coagulation and the deposition of a fibrinous substance.

Gentlemen, I have informed you, that the sac itself becomes intimately adherent to the neighbouring textures, nor do these parts remain unaffected; sometimes they are simply displaced, or compressed; sometimes they are thickened; sometimes they are more or less absorbed; in certain cases they ulcerate; in others, they slough. Thus, from the compression of an aneurism of the aorta, a large portion of the ribs and sternum is frequently absorbed; and if the aneurismal swelling make its way through the ribs in the back, it may displace the scapula, a remarkable example of which was under the care of Dr. Pinckard and myself, about a year and a half ago, at the Bloomsbury Dispensary. Frequently the bodies of the vertebræ are destroyed, and the tumour may even penetrate the spinal canal, and press on the medulla so as to occasion paralysis, though this is undoubtedly a rare occurrence. I now hand round a preparation, which is an aneurism of the descending aorta; the vertebræ have been so injured by

the pressure of the aneurismal tumour, that the medulla is exposed; if you look into the sac, you will see the spinal marrow completely denuded. In this instance, the scapula was displaced, but the aneurism did not burst externally in that direction, for another part of it gave way, the blood flowed into the trachea, and thus the patient was destroyed.

When an aneurism of the aorta injures the vertebræ by its pressure, it is curious to observe, that it generally spares the intervertebral substance, which has a greater power than bone of resisting the destructive effects of pressure upon it. In this preparation, you will observe that, though the bodies of the vertebræ are considerably impaired, the intervertebral substance itself is perfect, and this is commonly the case. The pressure of an aneurismal tumour does not produce the removal of a cartilaginous texture so easily as it does the substance of a bone.

Sometimes aneurisms of the aorta burst, and pour their blood into the viscera of the chest, or abdomen. They may make their way into the trachea, the œsophagus, or the air cells of the lungs; and they have been known to burst into the pulmonary artery, and occasionally into the right auricle of the heart. Instances are on record of all these occurrences. Aneurisms of the aorta, in fact, frequently burst into the œsophagus, the trachea, the bronchi, the air cells of the lungs, the stomach, or different portions of the intestinal canal. The patient may be destroyed by the aneurism bursting into any of the organs I have mentioned. Sometimes the vena cava is obliterated by the pressure of the aneurismal tumour. In the case from which this preparation was taken, where there was no regular cyst, where, in fact, the blood had passed down into the concavity of the sacrum, its pressure obliterated the vena cava at the point where it receives the common iliac veins. Sometimes an aneurism is found to produce great changes in the texture of an important nerve in its vicinity, flattening it into the form of a riband, and totally disorganising it. I have seen several cases, in which the popliteal nerve was so flattened and altered, as to be hardly known again. In one particular instance, which fell under Cruveilhier's notice, and of which I now show you a plate, the pressure of an aneurism of the aorta had obliterated a portion of one of the pneumo-gastric nerves, which was flattened and so altered that no appearance of nervous tissue was discoverable in it. In the same case another fact is illustrated, namely, the obliteration of a large vein; for here, you see, the left subclavian vein, where it passes across the back of the tumour, is rendered quite impervious, and almost effaced. Here, then, you have two important facts relative to aneurism well illustrated; but the case furnishes additional instruction, for it teaches you, that a patient with an aneurism may have more swellings than one of the same nature. In

fact, the patient, whose case we are considering, had an aneurism of the arch of the aorta, and another of the descending aorta. The case also exhibits another fact, which is, that the patient was not carried off by the bursting of the aneurism, but by its pressure on an important organ, namely, the trachea. Now, when an aneurism presses upon the trachea, it frequently makes its way into that tube by ulceration, and the patient dies of hæmorrhage, or is suffocated by the quantity of blood obstructing the entrance of air into the lungs; but here he was suffocated by the pressure of the tumour. However, you may observe that ulceration was commencing on the lining of the trachea at the point where it divides into the bronchi. I never heard of any other instance, in which so important a nerve as the pneumo-gastric had suffered in the manner represented in the engraving, and, no doubt, this circumstance influenced the symptoms, for the patient was incessantly vomiting, and had frequent swoons and profuse cold sweats.

Occasionally, the pressure of an aneurism on a bone, instead of causing the absorption of the osseous texture, will thicken the periosteum; and, under these circumstances, new osseous matter may be thrown out so as to surround more or less of the sac. With respect to the effects produced by the pressure of an aneurism on bone, it merits your attention, that when absorption of that texture is produced, the process differs from caries in not being attended with the secretion of purulent matter: there is a simple removal of the osseous texture; and generally, if the cure of the aneurism be accomplished, the change in the bone does not afterwards give trouble. Generally speaking, it does not prevent the patient's recovery; though, now and then, cases occur, in which the patient is obliged to submit to amputation after the cure of popliteal aneurism, on account of the extent of mischief in the bones and joint of the knee. One curious effect of an aneurism, occasionally noticed, is a dislocation: thus, the sternal end of the clavicle has been sometimes displaced by an aneurism of the arch of the aorta.

After the explanations which I have given, you understand, that when an aneurism has made its way through all the coats of the artery, and through the cellular sheath of the vessel, it is still generally surrounded by whatever textures happen to present themselves. Thus, in an aneurism of the aorta, you will frequently find, after this stage, that the blood is bounded by the sides of the œsophagus, by the trachea, by a portion of the substance of the lungs, or by the naked vertebræ, deprived of their periosteum. In the last lecture, I showed you one of Mr. Hodgson's engravings, in which a portion of the lungs was represented as forming the boundary of an aneurism of the aorta; and here is a preparation exhibiting the same fact. In another case, a preparation from which I now pass round, the tumour ultimately burst into the cavity of the

pleura; but, I believe, the existence of the aneurism had never been suspected during the patient's lifetime, for there was no external tumour, and no pulsation perceptible.

When an aneurism is about to burst externally, a small conical eminence is usually formed at one part of the swelling: a kind of rising, or *pointing*, takes place, and the apex of the prominence becomes a slough. These conical risings, which I have seen, varied in diameter, at their base, from the size of a shilling to that of a sixpence. On the loosening of the slough, the patient begins to bleed; sometimes he is carried off suddenly by one immense gush of blood; but, in other instances, he is destroyed more gradually by repeated returns of hæmorrhage. When an aneurism is about to burst into a cavity invested by a mucous membrane, like the œsophagus, intestinal tube, or bladder, the aperture is generally formed by ulceration; but if it burst into a serous cavity, the aperture is not formed by ulceration, but by a sort of crack or fissure: this is what takes place on the peritoneum and pleura. In the skin, the aperture is formed by a slough.

All these circumstances have been well ascertained by pathologists; and you will find an excellent explanation of them in Mr. Hodgson's work, which is one of the clearest and best that has been published on the subject of aneurisms.

Here is a specimen of three small aneurisms on the root of the aorta, just above the semilunar valves; and one of them, small as it is, occasioned death by bursting and permitting the escape of the blood into the cavity of the pericardium. This case teaches you, that though the aneurism may be small, yet, when it is so situated, it is liable to break in an early stage, and produce fatal consequences. Here the pericardium was completely filled with blood, the action of the heart obstructed, and the patient lost his life. You see, it was the pressure of the effused blood on an important organ that caused death, and not the pressure of the sac itself.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XII.

Hepatic Abscess—Use of Iodine—Painter's Colic—Gangrene of the Lung.

GENTLEMEN,—The case presenting symptoms of hepatic abscess opening into the right lungs to which I alluded on a former occasion, has within the last few days been doing remarkably well. You will recollect, that the last time I spoke of this man's case he was in a very precarious state; he had constant and

harassing cough, with copious expectoration of puriform matter, extensive dullness of the lower part of the right side on percussion, and symptoms of a cavity in the lung, which we considered to be the fistulous opening through which the contents of the abscess were discharged. There was one peculiarity connected with this and other similar cases, and he stated that it had been invariably present during the progress of his complaint. When he assumed the erect posture he had neither cough nor expectoration, but when he lay on his back or one side a fit of coughing with expectoration came on. This is a symptom the nature of which is easily understood, when you remember that, in the erect posture, the matter cannot easily find its way into the lung and excite pulmonary irritation, and is one which has been frequently observed in these cases. Of late this man's appearance has been very much improved, his breathing is much easier, the remains of the tumour in the right hypochondrium are scarcely apparent, the lower part of the right side sounds almost clear on percussion, and, lastly, the phenomena indicating the existence of a cavity have been gradually disappearing. We have, therefore, gentlemen, a correspondence between the general symptoms and the local signs, and this is the best and surest mode of establishing a correct diagnosis. It will not be deemed too sanguine in me, under such circumstances, to hope for a favourable result in this case, particularly when you recollect, that the bursting of an hepatic abscess into the lungs is one of the safest modes in which the disease terminates. It is obvious, that, under such circumstances, particular attention should be paid to diet; we have been giving this man nutritious food to support his strength, we also prescribed an infusion of bark and diuretics to act on the urinary system.

There is one remarkable feature in this case which it is difficult to explain, namely, that of late the cough has become more troublesome, though the lung is getting clearer every day. It would seem as if the removal of the mucus and pus, which protected and sheathed the bronchial membrane from atmospheric contact, was a source of irritation. To remove this we have ordered him to take the extract of conium, and he appears to have derived considerable benefit from its use.

There is another case above stairs, under the care of Mr. Martin, on which I shall make a few brief observations. The patient is labouring under an attack of chronic bronchitis, producing an emphysematous state of the lung, and an obstruction to the free circulation of the right side of the heart. What renders this case interesting is that, in addition to the foregoing symptoms, the patient has a tumour in the right side which, on accurate examination, turns out to be an enlarged liver, but which very closely resembles that which would be produced by an empyema of the right side. Now, in cases of emphysema of

the right lung, where there is considerable dilatation of the air-cells, the dilating force may so act on the diaphragmatic floor of the thorax, that we may have a displacement of the liver as in empyema. But this does not militate against the value of this sign in empyema, because if it be *empyema* you will have increased dullness of sound on percussion, but if it be *emphysema* there will be increased clearness, and this is sufficient to form a diagnosis. Such is the case of this man, but there is this peculiarity attending it, that we cannot pronounce before death whether there is enlargement of the liver or not. In many instances of disease of the heart, sufficient to cause obstruction to the circulation of the right side of that organ, we have a mechanical subsequent enlargement of the liver, and in some cases dropsy and swelling of the jugular veins, so that we may be certain that there is distinct hyperæmia of the liver. It is of importance to be aware of this fact, and to hold in memory what many practitioners appear to forget, that there is some other cause for the dropsy besides disease of the liver, and that it is necessary to know that in some instances this disease is consecutive to obstruction of the circulation of the right side of the heart. I have known many instances in which there was a great deal of confusion on this subject, and much consequent disagreement amongst medical men. I have seen cases where the patient had disease of the heart and enlarged liver, and one practitioner said it was beyond doubt liver disease, another said it was disease of the heart. In such cases we have generally found that the facts stated by Andral were correct, namely, that *the size of the liver varied in proportion to the state of the circulation*. If you relieve the venous plethora the hepatic tumour will subside, but it will again reappear when the action of the heart is excited, and the obstruction to the circulation becomes excessive.

We have in the house at present several cases under the use of iodine, to which I beg your attention. I have alluded before to the case of a woman named Green, who has been in the Fever Ward under the care of Mr. Martin. This woman first had symptoms of enteritis and peritonitis, she then had diarrhoea and subacute peritoneal inflammation, and, in the last place, enlargement of the belly, and swelling of the lower extremities. We employed the antiphlogistic treatment, but finding that it did not answer our expectations, and that the dropsy still continued, we had recourse to iodine. We ordered her to rub in daily a certain proportion of an ointment, composed of ten grains of iodine and one drachm of the hydriodate of potass, to an ounce of lard, and to use the iodine mineral water internally. She has been taking these for some time, and, as you perceived, with very great benefit, the improvement was remarkable on the second day after she began to use it, for an immense flow of urine

took place, and the anasarca of the lower extremities began to decline considerably. We have very great reason to think favourably of the efficacy of iodine as a therapeutic agent in the treatment of dropsy. In consequence of its energetic action on the system, we have reduced the dose in this woman's case to one half of the original quantity taken, but the effect, as you may have remarked, continues the same. We are also giving the iodine solution in two cases of dropsy in the male chronic ward, and in both its administration has been followed by a copious diuresis. I think the form we employ, namely, the iodine mineral water, the most eligible and easiest mode of exhibiting this powerful medicine, as it is a more agreeable, and, I think, certain mode than any other. By dissolving one grain of iodine and ten of the hydriodate of potass in a quart of distilled water, you have a solution, which is easily taken, and acts with surprising efficacy in such cases.

Before I proceed to direct your attention to an affection of the lungs, which has terminated in gangrene and abscesses, I wish to say a few words on some cases of painter's colic, which you have noticed in the wards. Painter's colic is a disease which is not uncommon in this country; during this season we are seldom without a case of it in the hospital, but it appears to me that with respect to its nature a great many erroneous opinions prevail. Some persons maintain that it is a mechanical obstruction of the intestinal canal, depending on spasm of its muscular fibres; and indeed when you look at the affection superficially, this opinion seems very reasonable, for there is great pain, constipation, spasm of the abdominal muscles, and contraction of the belly in general, which appears as if it was pressed backwards towards the spine. The coincidence, then, of pain, spasm of the superficial parts, and contraction of the belly, with a state of obstinate constipation, would lead a casual observer to think that painter's colic was a mechanical obstruction, depending on spasm, and that the constipation was to be attributed to the same cause. This doctrine also has been further countenanced by the occasionally favourable effects of remedies calculated to remove spasm, as hyoscyamus, opium, and tobacco. It is not, therefore, very extraordinary, that many persons are of opinion that painter's colic is spasm of the muscular fibres of the lower part of the digestive tube. Another class of practitioners, particularly those connected with the school of Broussais, maintain that this affection is nothing but an enteritis, or inflammation of the mucous membrane of the intestines, and to be treated as such, although this is not the theory of the founder of the doctrine. In the present state of medical science, we have not many facts in support of these opinions; painter's colic seldom proves fatal in this country, and in those cases where dissections have been obtained, the patients have died of

some other disease. We seldom examine the body of a patient whose death has been entirely occasioned by this disease, and hence it is only under the circumstances above mentioned that we have an opportunity of investigating its pathology. Andral has recorded some cases of this kind, where he had an opportunity of examining the intestinal tube, and you will find that he states that the canal was free from obstruction. The next point stated by Andral, and it is one which is decidedly established, is that in such cases there is either *no inflammation* at all or only a slight blush of vascularity, quite insufficient to account for the violence of the symptoms. So far, then, as pathological anatomy goes, we are neither to consider painter's colic as an inflammation of the mucous membrane of the intestinal canal, nor as spasm of its muscular fibres. Indeed, with respect to the former opinion, if you consider the case attentively you would be surprised if dissection should prove it to be an enteritis. We have, to be sure, severe pain in enteritis, but never so intense nor of the same character as in painter's colic. Again, in enteritis there is generally disease of all the coats of the intestines, and high fever. This does not occur in painter's colic; there is no indication of an active inflammation of the digestive tube, and we have no fever present. So far, then, as the subject under consideration goes, it appears that many persons have painter's colic without any appearance of intestinal disease, that in some cases we have a slight degree of vascularity or congestion, but not sufficient to account for the symptoms. What then is the real nature of the disease? It appears most probably to be a nervous affection of the intestines, and it is also likely that the spinal system is also engaged. There is another doctrine also with respect to painter's colic, which is by no means fully established, namely, that the lead is absorbed into the system, and produces an astringent effect on the mucous membrane of the intestines, giving rise to pain and constipation. That the nerves, or at least that the spinal cord is affected in this disease, we have direct proof from the paralysis of the arms, which so frequently occurs during the progress of the complaint, and from the circumstance, that this paralysis is frequently removed by means calculated to act on the spinal marrow. We do not, however, in those cases find on dissection any marks of inflammation in the brain or spinal cord, so that we must class this disease with that singular group of affections to which we give the name of neuroses, that is lesions of function without any perceptible organic change.

In this country we generally observe painter's colic appearing in two forms. In the first of these we have great pain in the belly and obstinate constipation, but there is no paralysis or affection of the senses. In the other form which is much more severe, the pains are dreadful, the constipation constant,

the retraction of the abdominal muscles very great, and after these symptoms we frequently observe convulsions of an epileptic character, partial or total blindness, or deafness and coma. These continue for a period more or less considerable, and then subside, and the patient recovers. We have had many cases in hospital where the disease proceeded so far as to cause blindness and deafness with convulsive fits, and we have observed that such cases were to be treated differently from those of the former class, and that it was necessary to modify the plan of cure according to the form in which the disease appeared. When the disease appears in the simple form, we trust principally to the use of tobacco injections and purgatives, and employ the hip bath as a most valuable auxiliary means. There is a great deal of benefit in such instances derived from the use of tobacco, which I believe was first employed by Dr. Graves in the treatment of painter's colic in this country. The next thing we have recourse to is catharsis, as it has been proved by experience to be very efficacious, and this is a fact worthy of notice. If painter's colic were, as some of the disciples of Broussais think, a case of enteritis, the purgative plan would not do, it would only aggravate the disease. But, what is the fact in cases of painter's colic? The mucous membrane of the digestive tube, so far from being irritated by the exhibition of purgatives, is capable of bearing enormous doses of medicine, and experiences the most singular benefit from their employment. This system of severe purgation is that which has been pursued for many years in the Hospital of La Charité at Paris with decided advantage. In this hospital we are in the habit of prescribing castor and croton oils with a small quantity of tincture of opium, and we find that as soon as the bowels yield the symptoms are altered for the better. In a few cases where the pain has been very violent, we have recourse to the lancet, not for the purpose of subduing inflammation, but in order to check the intensity of spasmodic action. We generally trust to purgatives as we find an improvement in the patient's symptoms generally succeed their operation, and we repeat them according to circumstances. As I mentioned before, where the spasms are excessive we derive much benefit from venesection, and I have seen several cases where we could effect no good with the tobacco enmata or purgatives until blood had been drawn. In the violent form of the disease, where there are deafness, blindness, coma, and convulsions, I believe we cannot lay down any fixed rule with respect to treatment. We have, however, pursued the following plan. The head is to be shaved and blistered, for we have found that much good may be done in this way. There is one curious circumstance which occurred in this hospital some time back, which I shall mention here. We had a patient with painter's colic, who was labouring under profound coma, and I determined to try

whether an opiate would increase or diminish it, from my strong suspicion that the coma was, like the other symptoms of this disease, unconnected with congestion or inflammation. We gave him a full opiate in the evening, and next morning he was found sitting up in bed quite free from coma, and with his sight and hearing (of which he had been deprived) completely restored. I do not intend to draw any conclusions from this single case, but I think it is an interesting clinical fact.

I now, gentlemen, draw your attention to a very important case of thoracic disease, and one in which we have been enabled to form a correct diagnosis by means of the stethoscope. You remember a man of the name of Crowley who was for some time under the care of Mr. Ellison. He was admitted with pulmonary symptoms, on the afternoon of the 13th, and having been seen shortly after his admission by Mr. Ellison, it struck this gentleman immediately that there was something very peculiar in the case, and that it was no common inflammation of the lungs. He therefore called at my house the same evening, mentioned the circumstance to me, and said that he considered it a case of extreme severity, and that it was either an intense and rapid pneumonia, or effusion into the pleura. I shall give an outline of the case to show you how correct he was in his suspicions. It appears that four days previously, that is on the 9th, this man had been in a state of extreme intoxication. Here I must remark that Crowley had been a temperate man until the appearance of cholera, when he lost his wife, and then fell into a nervous desponding state, to relieve which he took to drinking, and has been since that time in the constant abuse of spirituous liquors. This is no unusual thing, gentlemen, since cholera visited this city, for I have known many instances of persons, not only of the lower order, but also of the respectable classes in society, getting into a habit of drinking from a fear of being attacked by the epidemic. I know a gentleman, who as a preservative against cholera drank brandy every day in considerable quantities, increasing the dose until he brought on a dangerous hæmoptysis. However, the history of the present case is, that the patient in a state of intoxication fell into the canal, and having remained for some time in his wet clothes, was attacked on the next morning with great fever and pain in his right side. On the 11th he went to a dispensary when the nature of his complaint was overlooked; he got some useless and inefficacious medicine, and was then sent away.

The first thing which attracted Mr. Ellison's attention to this case was the extreme prostration of strength which the patient manifested on his admission. It was next observed that his sputa were of an extraordinary kind, and different from those commonly seen in cases of pneumonic inflammation. They were of a dark red colour, and floated in an abundant quantity of fluid, which bore a strong resem-

blance to bloody serum. You will recollect that I directed your attention to this circumstance on several occasions during the progress of the disease, and stated that I had never seen sputa of a similar character. Mr. Hudson mentioned to me, that he had seen something of the same kind in a case which afterwards turned out to be gangrene of the lung; but I believe it is a thing very seldom witnessed. The respiration in this case was extremely feeble and bad; there was constant pain in the chest; dulness on percussion over the whole anterior and lateral portion of the right lung, except at the upper part, where the sound was somewhat clear. The patient was bloodied to the amount of a few ounces, had his chest cupped, and took calomel and opium. On the next morning we found him extremely ill. He had raved and tossed himself about in bed during the night, and moaned frequently. *The whole lung was now dull on percussion, and the upper portion of it, all of a sudden, presented the phenomena of hepatisation without the occurrence of crepitating râle.* He had twenty leeches to the axilla, and, as he felt extremely low, a small quantity of wine. In the evening he was again visited, and found to be rather worse; his breath had become more decidedly offensive since morning, but it was not a mercurial fœtor, nor was it the smell which accompanies gangrene of the lung. His pulse had now become extremely rapid, and his respirations amounted to fifty in a minute. On the 15th he was found lying on his left side, his countenance sunk and ghastly, and his tongue very much loaded. The phenomena of the chest were the same except that *bronchial respiration was more distinctly heard*, and there was an extensive mucous râle at the root of the lung. Some time before he died we found a considerable gurgling and cavernous respiration in the lower part of the affected lung; and the diagnosis we made was, universal solidification of the lung, and abscess in its inferior portion. The patient sunk on that night; and, on dissection, our diagnosis was found to be perfectly correct. Here, gentlemen, you see the diseased lung; you perceive that it is extensively solidified, and that a very large abscess occupies its lower portion down to its diaphragmatic surface. Observe, the abscess is bounded below by the serous membrane alone, which separates it from the pleural cavity and diaphragm; and in the centre of this abscess you may perceive an extensive slough which I can remove with my finger. On making further examination, we found the liver enlarged, a circumstance which was taken notice of during life, and the mucous membrane of the stomach in a state of acute inflammation. Examine it for yourselves; it is an excellent specimen of gastric inflammation. Here is the cardiac orifice with its mucous membrane thickened and vascular; and here is the lower portion of the œsophagus with its cuticle softened and abraded. It is

necessary to notice these circumstances as connected with the history of the case, and the complete failure of the treatment adopted.

Gentlemen, this is a case of importance in many points of view. You seldom have an opportunity of seeing so recent a case of gangrene of the lung, or one which was marked by so rapid a fatality. In the majority of cases the gangrene is very much localised; nature makes an effort to set bounds to the mischief, and the patient does not die so suddenly. But, in this instance, the whole of the lung is struck, all at once, with severe inflammation and extreme congestion; it passes rapidly into a state of disorganisation: in addition to this, the patient has intense gastritis; and the combination of these two affections, in a system broken down by habitual intemperance, will easily explain the extent of the lesions discovered after death. The ordinary diagnosis of gangrene of the lung is drawn from the existence of a peculiar symptom, namely, the fœtor of the breath. To such as have not had an opportunity of seeing a case of gangrene of the lung, and becoming acquainted with the peculiar stench attending it, I must say that there is not perhaps another smell so dreadful. In this man's case the fœtor was also remarkable, but not to such an extent; and from this I am led to conclude, that the peculiar stench which accompanies gangrene of the lung only occurs when the disease has been of some duration. If this man had lived longer we should have perceived this smell; but he died before its occurrence, in consequence of the combinations of severe gastritis and extensive solidification of the lung, with the phenomena of gangrenous abscess. You perceive, then, that we may have gangrene in the lung without the characteristic fœtor of that disease, or, at least, without that peculiar stench which is generally known to attend it. Hence it was, that, in consequence of its absence, we only diagnosed abscess.

Every thing in this man's case strongly tended to point out the decided prevalence of a typhoid condition. In the first place, he had a constitution broken down by intemperance; in the next, he had several important organs simultaneously affected, and his fever and the condition of the lung were overlooked in the commencement, and permitted to attain an unmanageable intensity by neglect.

This case further illustrates two stethoscopic points. The first is, *the increase of bronchial respiration coincident with the formation of an abscess.* We have shown in the Report of this hospital, in the fifth vol. of the Dublin Hospital Reports, that the increase of bronchial respiration may arise from diminution of disease. Now, if in place of resolution we have permeability from an abscess, the same result will follow. The next point is, *that here we had a rapid dulness without preceding crepitating râle;* and yet the disease

is not pleurisy with effusion, but solidification. We must, then, make this exception to Laennec's and Andral's diagnosis.

MEMOIR

OF SOME FACTS OBSERVED AT THE HOPITAL DES VENERIENS.

BY PHILIPPE RICORD, D.M.P., SURGEON OF THAT HOSPITAL, &c. &c.

Read at the Sitting of the Royal Academy of Medicine on the 6th March, 1833.

TRANSLATED BY ALEXANDER THOMSON, M.B. OF ST. JOHN'S CAMBRIDGE.

CHARGED with a numerous service at the Hôpital des Vénériens I have been enabled, owing to the changes going on in my wards, to see a great number of patients, and thus to make observations that have led me to some results that I am about to submit to-day to the judgment of the Academy.

I think I can affirm that in a hundred of the female patients in the venereal hospital, sixty are affected with discharges, either acute or chronic *; blennorrhœa however being much more common than blennorrhagia.

Most of the patients affected with chronic discharges are only sent to the hospital by the dispensaries when they have some other syphilitic symptoms, either primitive or secondary. Thus, in the commencement, when we questioned the women on their entrance, and when we perceived the discharges under which they were labouring, they stated that they had had whites for several years, and that all the treatment hitherto employed had been unavailing. It would appear, indeed, that, in a great number of cases, an infinity of means having been unsuccessfully employed, all treatment had been abandoned in their case, and that they had been sent most commonly to the hospital with their blennorrhœa as soon as the other symptoms had appeared.

It is known, and daily experience confirms it, that the women, under the inspection of the police, treat generally the venereal disease with the greatest levity, and would not trouble themselves about it, if there did not exist dispensaries to arrest them when they become sinks of infection. This indifference we must say comes from the facts, that three-fourths of the symptoms occur in them without producing pain, or even uneasiness, and that they seek to protract as long as they can their debauches without troubling themselves about their treatment; this moreover being calculated to withdraw them for a longer or shorter

period from the exercise of their shameful calling, without however assuring them against a new infection, which frequently may supervene the day after their cure. Hence their repugnance at entering into the hospital, and their desire, when once there, to go out as soon as possible, cured or not. Every body knows, indeed, all the stratagems, all the means, frequently ingenious, they employ to lull the attention of the medical attendant, and to dissemble the symptoms that might retain them in the hospital, which they regard rather as a prison than as a place destined to restore to them their health. On the other hand, while these women long but for the day of their exit, the patients received in the civil wards earnestly demand to be retained until perfectly cured; these far from hiding a symptom, exert themselves to unfold the whole of them, and often, even not content with exaggerating those that exist, they bring forward such as are but the result of their terrified imaginations, or of a calculation for procuring a prolonged residence in the hospital.

In the midst of these difficulties, to frustrate stratagem and to avoid being imposed upon by deceitful complaints, the only thing to be done was to submit the parts of generation to a rigorous examination. To accomplish that, as had been done before me, I placed the patient on a bed, similar to that employed for the perineal operation for the stone, a bed serving likewise in the hospital for the excision of vegetations, and placing the pelvic limbs in a state of half flexion and of abduction, examined the genital parts with great care; but the examination could only be made on a great number, owing to the disposition of the parts as far as to a level with the carunculæ myrtiformes, and in the remainder only to a little beyond them; so that, in this manner, more than the upper half of the vagina and the neck of the uterus escaped in this investigation, which, on the day of exit, was frequently to afford them, erroneously, a certificate of health.

Convinced of the insufficiency of this mode of examination, I determined no longer to allow a patient to go out without having examined her, not only exteriorly but interiorly, by aid of the speculum †, an instrument capable of rendering visible the most remote parts of the vagina, as well as the neck of the uterus itself. The means doubtless was not new, but its general and universal application was undoubtedly so. From that moment I could affirm, that it was no longer possible to establish a rigorous diagnostic in venereal diseases in women without having recourse to this means of examination. From that moment I explained to myself how women, reputed to be healthy, had communicated the disease, and how a great number, who had retained dis-

* I have caused the *résumé* of these cases to be made by M. Chandru, élève interne of my service, to whose zeal and intelligence I gladly seize this opportunity of bearing testimony.

† I shall soon have the honour of transmitting to the Editor a description of M. Ricord's improved speculum, and the mode of applying it.—A. T.

charges, had remained permanent sinks of infection; from that moment I was enabled to study well blennorrhagia and blennorrhœa, and to determine the frequency of the different ulcerations, vegetations, &c. upon the neck of the uterus, or in the remote parts of the vagina.

The results I have thus obtained have induced me to conclude, that the dispensaries, established by the police for the public women, could only be illusory until such time as the patients should, without exception, be examined by the aid of the speculum; while, on the other hand, by employing this instrument upon all suspected women, and by no longer contenting ourselves with an external examination alone, *one might, by sending into the hospitals the great number that might be found thus diseased, and who previously would not have been suspected, prodigiously diminish the number of venereal diseases.*

I do not intend to treat here of all the local exterior characters of the general and sympathetic symptoms, of the complications, and of the progress of blennorrhagia, of blennorrhœa, of the different species of ulcerations, which all the authors have more or less accurately described; I mean only to indicate the points which have not been sufficiently dwelt upon, or which appear not to have been known.

The whole of the genito-urinal mucous membrane may be the seat of blennorrhagic discharge; this is a fact generally admitted in the present day; but some points in the extent of this mucous surface are much less frequently so than others. Yet the observation of two hundred patients has taught me that they are even more so than had been believed. I have been astonished indeed at the frequency of urethral blennorrhagia, and I never could conceive how Swediaur could even deny its existence, and how modern authors, of the highest merit, have considered it as *very rare*. It is true, that I have frequently been obliged to seek carefully for it; the pus remaining only a short time in a very short canal, placed obliquely in some patients, so as to favour its flowing out from the declined position of the *urethra urinarius*, and being, moreover, every moment, carried along with the urine, of which, in many cases, the emission is frequent, or appearing to come from the parts adjacent to the urethra. But bearing all the circumstances in mind, and making my researches at a favourable period, the indicator finger being introduced far back into the vagina, and made to compress the urethra from behind forwards, I have produced the exit of pus, or blennorrhagic matter, eight in twelve times. In the majority of cases, the affection of the vagina exceeded that of the urethra, but in some the urethritis seemed to predominate*.

All the women having purulent discharges from the urethra at the same time as from the vagina, have told me that these have been communicated to them, none have referred them to whites (*fleurs blanches*). Consequently, notwithstanding what has been said by some authors, the presence of urethral discharges may, in a great number of cases, throw light upon the diagnosis.

I have often found buboes, in an acute state, coincident with urethro-vaginal blennorrhagia, when there existed neither chancres† nor ulcerations upon any other point of the genital parts. Hitherto I have not found the same coincidence between vaginal discharges alone and buboes.

On examining the vagina, in the acute stage, with the speculum, I have found,

First. The mucous membrane only redder than normally in the whole of its extent.

2ndly. In some patients this redness, accompanied with much heat, sensibility, and a species of tumefaction, may be referred to what Fabre called *erysipelatous gonorrhœa*, (*gonorrhée erysipelateuse*), and we have seen it terminate by a species of resolution, without giving rise to any secretion; but, in the majority of cases, it has been the precursor of the discharge.

3rdly. In several women there existed prominent patches, varying in size, and of which the redness was very marked, and abruptly terminated, while the rest of the vagina preserved its normal colour, of a more or less pale rosy hue.

4thly. In some the mucous membrane of the vagina presented a crowd of reddish papulæ; in others it was only spotted.

5thly. These different states, however, coincided with vaginal secretions of different kinds; some transparent and mucous, others serous and reddish-brown; finally, others purulent.

6thly. In some of those in whom the discharge was reddish-brown, it sometimes became sanguineous; but then there was an absence of the epithelium on the reddest parts; there was in these parts erosion of the mucous membrane, still these erosions most frequently gave rise to a purulent discharge.

7thly. In one patient, of a marked lymphatic temperament, we found in an acute

of this memoir I have seen two cases of blennorrhagia, purely urethral, the vagina being perfectly healthy.

† From experiments made recently by M. Ricord, and of which an account will soon be transmitted, there is reason to believe that this observation is incorrect in a general sense. Buboes, it is true, occur with blennorrhagia, when no chancres can be traced, but in most cases it is more than probable that they are merely phlegmonous, and in many cases are actually extra-ganglionic.—A. T.

* In all the cases, of which there was here question, there was, as may be seen, urethro-vaginal blennorrhagia, but since the reading

vaginitis, the vagina carpeted with fleshy granulations, similar to the *luxuriant* granulations that are developed upon scrofulous wounds; this patient was affected with a very abundant purulent discharge. We have found in several patients affected with purulent discharges this state less developed, and appearing to depend upon a development of the inflamed mucous follicles.

8thly. Three patients affected with recently commenced purulent discharges, and sent to the hospital as having blennorrhagia, had ulceration of the vagina, of from three to six lines in diameter; ulcerations of a slightly funnel shape, with abrupt edges, and a greyish bottom. There existed nothing upon the external parts of generation.

9thly. The different lesions we have just indicated as existing in the vagina, we have also found upon the mucous membrane of the neck of the uterus, which in a great many cases has appeared to us to be alone affected; sometimes, however, the portion of the vagina immediately covering the os tincæ, was at the same time affected, but in a very marked manner, so that in uncovering the neck of the uterus by the aid of the opening speculum (speculum lorite), one might have thought he had been looking at a gland, and its prepuce affected with balanitis. It is known, moreover, that Hunter has compared blennorrhagia in women to balanitis in men.

10thly. With inflammation of the mucous membrane we have often found the neck hypertrophied, and in some cases, the body itself of the uterus has appeared as if slightly swollen; the secretions furnished by the mucous membrane of the neck have been the same as those of the vagina.

11thly. But in many patients who had, on their arrival at the hospital, puriform matter at the entrance of the vulva, without there having been symptoms of inflammation of the internal genital parts, patients who made the date of their discharges remount but a few days, the vagina has been found healthy in its whole extent, while the os tincæ, swollen and red round its orifice, permitted puriform mucosity to escape in very great abundance; in these cases, however, as Brugnone has already indicated, the blennorrhagia seemed to be solely uterine.

12thly. An observation we have made upon more than a hundred patients is, that the uterine secretions simply mucous, or mucopurulent, which are so frequently met with in the other affections of the vagina or of the uterine neck, and which are frequently designated under the name of whites (*fleurs blanches*), have always a glairy or white-of-egg consistence, that is to say, that they are united together in flakes*, which distinguishes them

from those of the vagina, which appear not to be agglomerated together.

13thly. In the acute state, I have found upon the neck of the uterus ulcerations seated, nineteen times in twenty, at the orifice, and once in the same number upon the circumference of the neck, more or less close to the blind sac with which the vagina surrounds superiorly the os tincæ. Of these last, of which I have six examples, four were seated upon the anterior and two upon the posterior face. It is conceivable, indeed, that if these ulcerations have been the consequence, as I think, of direct infection, that they must more readily have been produced upon the anterior than upon the posterior face, the public women presenting rather frequently a little anteversion, whence it results, that the posterior face of the neck is directed upwards, while the anterior face placed below, comes in contact with the penis, which tends itself to produce this turning backwards of the orifice, as has been observed by M. Lisfranc, to whom we are indebted for so many important facts upon the diseases of the uterus.

14thly. But the ulcerations we find so frequently upon the neck of the uterus, whatever may be their precise seat, may be eighteen in twenty times referred to the prominent ulcer (*ulcère saillant, ulcus elevatum*); frequently they are a species of fleshy granulations united together in groups; finally, in one patient, there existed true pustules, having a white, and, as it were, pappy summit. In some there was erosion of the mucous membrane, similar to that we have remarked as existing in the vagina; but finally, in others, and we possess six cases of them, ulcerations near the orifice running into the cavity, or placed upon the circumference of the neck, have presented us with all the characters attributed to true syphilitic chancres. It must be again called to mind here, that in these patients no exterior symptoms and no alleged uneasiness existed, that could have led to a suspicion of the existence of these lesions.

If we leave the acute to occupy ourselves with the chronic state, we find,

1st. This very remarkable fact, that in vaginal blennorrhagia the posterior part of the vagina is more affected than its anterior part, while most commonly the contrary occurs in the acute state.

2ndly. In some patients, the vaginal mucous membrane, as it were granulated, furnishes a milky secretion, spotting the linen with white

with me that the term is badly chosen; but the fact is, that neither the English nor French language has a single and powerful word for expressing this appearance. I have seen the secretion upwards of a hundred times, and think it may be characterised well, as having a white-of-egg appearance, and being found in larger or smaller tenacious elongating drops or masses.—A. T.

* The French word here is *flacous*, but M. Ricord, the author of this paper, and who has kindly examined the translation, agrees

stains, a secretion, which becomes, as it were, caseous in others, particularly when it remains in contact with the air, or when it is about to become evanescent; seen round the neck of the womb, it much resembles the sebaceous secretion met with in man between the glans and the prepuce; this state may be referred to the whites.

3dly. The vaginal mucous membrane permits also of the varying of a serous fluid, likewise spotting the linen with white stains, having sometimes a brown margin.

4thly. But most frequently in blennorrhœa, in those women we have examined, the vaginal secretions were purulent, yellowish, or greenish; in these cases the mucous membrane has been sometimes pale, and uniformly smooth, at other times thickened in different points, as it were deprived of epithelium, frequently woolly, reddish, as it were softened, and comparable to the conjunctiva in cases of chronic ophthalmia, or of eversion (*érraillement*) of the eyelids; this woolly state was particularly very remarkable in a patient in whom, each time we passed even very slightly the charpie brush over the neck, in order to remove the mucosity, it bled with the greatest facility, without there being, however, ulceration. This woman had at the same time a purulent vaginal secretion, and a very abundant purulent uterine catarrh.

5thly. Two patients have presented some patches in the posterior and most remote part of the vagina, much redder than the remainder of the mucous membrane, bleeding with facility, and giving rise to a purulent secretion. These patches were very superficially ulcerated, and led me to believe, previously to an examination by the speculum, in the existence of a slight uterine hæmorrhage.

6thly. With blennorrhagia we have found granulated vegetations, stalked vegetations, true cauliflower excrescences, upon all the points of the vaginal region of the uterus; sometimes the vagina alone has been affected; sometimes the neck of the uterus has been alone the seat of them; a more or less puriform and chronic discharge was the only symptom. In one of these patients, there existed, at the base of a vegetation, placed at two inches behind the myrtiform caruncule, a deep ulceration, with abrupt edges, but elongated, irregular, and appearing to be the result of laceration; in a word, one of those chancres called mechanical.

7thly. In the chronic state, and in the greater number of patients, we have found uterine catarrhs; the mucosity coming from the orifice was always transparent, and similar to the white of egg; the mucous membrane of the neck was most commonly pale, and free from swelling of the *os tinæ*; sometimes the mucosity was of a line, and in those cases there was frequently redness upon the neck, or even slight ulcerations of the orifice; in other cases, finally, the neck was red and hypertrophied; there existed erosions round

the uterine orifice, or else true ulcerations, either prominent or deeply depressed, like those of which we have already spoken above.

8thly. In one patient, who had had many children, and in whom the neck was very much developed, and had a very large orifice, nothing was seen at the exterior; but on separating the lips of the *os tinæ* by the aid of the opening speculum, ulcerations were perceived upon their interior face, which ran into the cavity of the neck.

9thly. All these different ulcerations have appeared to us as the most frequent source of the never-ending discharges, of which the deceitful name of whites does not hinder the contagious nature.

10thly. Finally, in some women, the purulent mucosity coming from the uterine orifice, has been the only appreciable symptom.

Two morbid examinations, made by me at the Hôpital des Vénériens, yielded me the opportunity of dissecting, in a woman thought to have been affected with blennorrhagia alone, a rounded funnel-shaped ulceration, with abrupt edges, with a bottom that was blackish upon the dead body, with an indurated base, and seated at about an inch and a half behind the caruncule myrtiformes; in the other, two other ulcerations having the character of the preceding, without the form, which in these was irregularly elongated, one upon the anterior lip of the *os tinæ*, the other ascending into its cavity; the latter, however, was a little rounder. In these ulcerations, and in the indurated tumour (engorgement) of their bases, nothing bore resemblance either to cancer or to scirrhus.

As to the contagion of the different lesions we have rapidly enumerated, the following is what we have up to this period had occasion to remark:

A girl sent by the police, already treated for more than a month back for a prominent, but not very extensive ulceration of the left commissure of the lips of the *os tinæ*, having at the same time a slight opaque uterine catarrh, slightly purulent, without very marked vaginal secretion, was examined by the aid of the speculum on the day of her exit. The vulva was found healthy, as well the adjacent parts and the vagina; the neck of the uterus was likewise healthy, and normal in bulk. Only the ulceration of the orifice was not completely cicatrised; there remained a point of the magnitude of the head of a large pin, which appeared to us, however, on the point of cicatrisation; the mucosity escaping from the uterus was transparent. The patient was considered erroneously as cured, and I dismissed her. A student in medicine, one of my *élèves*, who had formerly had connexion with her, and who had seen no woman for a long time, had at the moment of her exit connexion with her again, and contracted an *ulcus elevatum* at the base of the glans, and a bubo. The patient returned to the hospital the next day; we examined her carefully by aid of the spe;

culum, and we found nothing at the exterior or at the entrance of the vulva; the vagina was also healthy, but the neck of the uterus was red; it appeared a little swollen; the cicatrix of the ulceration was ruptured, and the ulceration itself, doubled in extent, secreted a puriform matter. The patient was retained in the hospital, and afterwards dismissed perfectly cured.

A woman, recently entered into the civil wards, affected with deep ulceration of the uterine orifice, but not much extended in surface, and giving rise to a purulent discharge, without there being any thing at the vulva, or in the vagina, told us that her husband had a chancre; this man happening to be also at the Hôpital des Vénériens, we were enabled to determine the existence in him of a chancre of the meatus urinarius.

Three patients, two in the civil wards, and one in those of the police, affected with purulent blennorrhœa coinciding with red and ulcerated granulations of the uterine orifice, but without chancre of the vulva or of the vagina, have told us spontaneously in praying eagerly for their cure, that whenever they had connexion with men, they communicated to them very intense blennorrhagia, but never chancres. In taking a retrospect of the facts we have observed during the space of six months upon a hundred and sixty patients, renewed every eight days, we have found,

1st. That the vulva was more frequently affected in blennorrhagia than in blennorrhœa;

2ndly. That in chronic discharges, the deep-seated parts of the vagina, the neck of the uterus, and its cavity were on the contrary more frequently diseased;

3rdly. That the different ulcerations were most frequent in the parts of the vulva situated anteriorly of the carunculæ myrtiformes, then upon the neck of the uterus, and lastly in the deep-seated parts of the vagina;

4thly. That vegetations were met with in the following order; on the vulva, the vagina, and the uterus;

5thly. That the different lesions, in the acute state may exist at the same time in different points;

6thly. That acute affections associated with others pre-existing and chronic, were speedily cured, without the latter having been influenced by them;

7thly. That in some cases, on the contrary, the chronic state was rendered more intense by the recent disease, which most commonly rendered the case more serious.

8thly. That the different lesions tended to produce similar lesions by contagion*, and

that at least, in the present state of our knowledge it must not be admitted that a simple blennorrhagia in a woman † can give rise to chancres in the man.

9thly. Finally, that a woman affected at the same time with blennorrhagia and with chancres, may, by having connexion with several men, give blennorrhagia alone, chancres alone, or these two affections simultaneously.

In coming to some points of treatment of the different lesions, of which the vulva, the vagina, and the uterus, may be the seat; permit me to say, that placed in the venereal hospital without preconceived ideas, and without any exclusive system, my intention is to observe rigorously the facts, profiting at the same time by the modern theories and the experience of the old observers.

Not admitting with Duran, so justly blamed by Fabre, that all discharges in women, acute or chronic, are of a syphilitic nature, and that there are no whites, whatever may be the period of their origin, that do not depend upon a venereal principle, I think it however prudent, even though it should be thought with Hernandez, that gonorrhœa is not identical with the pox, to regard with distrust every abnormal discharge proceeding from the vulva, particularly in public women, in as much as these discharges, of whatever nature, are generally contagious‡. But while we desire that every discharge should be carefully treated, admitting with Bell and others, that local treatment is the most efficacious, and ought to be placed in the first rank, we employ one which has in it nothing specific, nothing applicable rather to the syphilitic than to any other principle, and which we may, by modification, apply to all cases, leaving the particular principle, or the special complications of such and such a discharge to be subsequently combated by general means.

In the acute stage, whatever may have been the symptoms or their cause, antiphlogistics have succeeded well with us; but we have particularly derived great advantage in many circumstances from bleeding from the arm, so much and so deservingly recommended by our master and friend M. Lisfranc. Indeed, as he has so frequently proved in his clinical lectures, bleeding from the arm in diseases of the pelvis, particularly in those of the uterus and of its appendages, is far preferable to leeches applied to the neighbourhood of the diseased parts. However, when leeches have

† It will be seen by M. Ricord's next paper on the inoculation of *pox matter*, that there are gonorrhœas which cannot produce chancre even on inoculation, and that it is highly probable that no gonorrhœa can do so if it be not accompanied by a manifest or hidden chancre.—A. T.

‡ By contagious, M. Ricord here means what can produce gonorrhœa, as he informs me, for he thinks now that nothing but chancrous matter can produce chancre.—A. T.

* M. Pailloux, a very distinguished *interne des Hôpitaux*, who has been attached to my service, has collected carefully, in the men's wards and in those of the women who are under my care, some very valuable observations on this subject.

been requisite, we have caused them to be always placed for diseases of the vulva, of the vagina, and of the uterus, above the ligaments of Fallopius, and for those of the anus and of the rectum, upon the sacral region. In this manner we avoid the virulent secretions of the genital parts or of the anus coming in contact with the leech bites, and transforming these into very tedious and very difficultly curable ulcers, which frequently occurred to us in the commencement, when we caused the leeches to be applied in the fold of the thighs, or around the anus in patients affected with virulent discharges.

Again following the principles of M. Lisfranc, we have preferred having recourse to entire baths, they are generally more useful than seat baths, which frequently produce congestions in the pelvis.

Emollient injections are sometimes hurtful on account of the introduction of the extremity of the syringe; we replace them in such cases by charpie steeped in emollient injections placed at the entrance of the vulva, and frequently renewed, for the heat of the parts speedily renders these decoctions sour, and gives them irritating properties.

I shall dwell no longer upon what regards the acute stages of discharges, or of other lesions of the genital parts; my intention, I repeat, is not at present to make a treatise, *ex professo*, but only to indicate some points which have appeared to me deserving of attention.

As soon as the acute stage has been overcome, as the introduction of the speculum without pain is possible, the vagina and the neck of the uterus must be examined, in order that we may know whether there does not exist some indication to fulfil, such as excisions of vegetations, cauterisation of these same vegetations when they cannot be cut, cauterisations of the different deeply-seated ulcerations, and finally, treatment of the vaginal and uterine discharges.

For the examination of the vagina, an *entire** speculum, of a bulk proportionate to the parts, is preferable: it allows of all the vaginal mucous membrane, which unfolds before it as it is pushed forwards, being seen; but for the examination of the neck of the uterus, the opening speculum is better adapted; for it has happened to me, with the entire speculum, not to have seen ulcers seated upon the posterior face of the neck of the uterus, or to permit other ulcerations seated in the blind sac of the vagina around the os tincæ to escape my notice, or even not to have been able to see the os tincæ in the aperture of the instrument.

An observation that we have very frequently

had opportunities of making is, that the neck of the uterus, examined with the opening speculum, has not the same appearance or the same form as with the entire speculum. Attention must be paid to these differences, for, with the first instrument, the os tincæ may appear hypertrophied, while, with the second, it will present its normal bulk.

The following, after all, is the local treatment that enables us to dismiss, cured, the greater number of women affected with ancient and obstinate, simple or complicated, discharges, with lesions of the vagina, of the os tincæ, and, in some circumstances, with lesions of the uterine cavity.

I have almost generally renounced injections. Before we were so scrupulous in our examinations and in our dismissals, the women, paying little attention to their discharges, never gave themselves the trouble to make these injections. Since they have been convinced that they will not quit the hospital until they are perfectly cured, they have submitted to them, for the most part, with regularity, but, in the greatest number of cases, without any conceivable satisfactory results. In many patients, the injection does not reach so far as the neck of the uterus. M. Parent du Châtelet has told me, that he had assured himself of this fact, by placing upon the os tincæ a plug made of charpie, and causing, subsequently, a coloured injection to be administered, which did not stain the charpie. I know, however, that injections may be made to arrive at the most deep-seated parts of the vagina, by placing the pelvis so that its superior may become momentarily its most declined part; but even though injections may be well administered, the liquid remaining in the place too short a time acts but little, or even not at all; hence I have given the preference to the permanent application of liquids by means of charpie† imbibed with them—charpie that I make to bear upon all the diseased points of the deep parts of the vagina, and which I leave in place from twelve to twenty-four hours, according to the state of the parts and the greater or less abundance of the secretions. Then we have vaginal discharge without lesion of the mucous membrane. If that discharge is not great, a plug of charpie, steeped in a concentrated solution of acetate of lead‡, is introduced into the cavity of the vagina by aid of the entire speculum, and it is not replaced until the expiration of twenty-four hours. The

† Some persons have employed sponges.

‡ The ordinary dose of acetate of lead for the solution used by M. Ricord is half an ounce for a pound weight of water, in cases where the acute state is recently passed, and one ounce to a pound in chronic cases. We give the preference to this liquid in most cases; however, all those that have been recommended may be employed in the same manner.

* M. Ricord has since found by experience that the opening speculum is even preferable in this case, and now never uses the entire speculum.

discharge, is it abundant? The plug placed in the same situation is renewed twice a-day. A great number of patients whom we had caused to take astringent injections of every kind for a long time without success, have gone out cured after fifteen days' continuance of this treatment alone, aided by repose and regimen. The mucous membrane, is it covered with prominences similar to pale spongy unhealthy-looking granulations? Is it softened and woolly? The introduction of a plug of charpie, steeped in a mixture of twelve parts by weight of water to one part of acidulous nitrate of mercury, and left, according to circumstances, ten minutes, a quarter of an hour, half an hour, an hour, or even more, to be subsequently replaced by a plug steeped in a concentrated solution of acetate of lead (*Eau Blanche* of M. Ricord), has frequently well succeeded with us. For the time of leaving off the diluted acidulous nitrate of mercury, we must here take into consideration the condition of the parts, and leave it so much less time as we have to deal with more irritable women, and an adjacent lesion in an acute state; otherwise more irritation than may be desired for giving a spur to the chronic state may be induced, and thus more harm than good may be the result.

Have we ulcerations of the vagina or uterus to treat? Very frequently the dressing, with the acetate-of-lead plug placed upon them, suffices to induce their cicatrisation. Are they accompanied with induration and swelling of the parts on which they are seated? Small revulsive bleedings are very efficacious. Are they atonic? Whether they be prominent or depressed we cauterise them with the pure acidulous nitrate of mercury, directed upon them by aid of the charpie brush: this has appeared to us preferable to every other caustic. As soon as the cauterisation is accomplished, we place upon the cauterised points some charpie imbibed with the solution of the acetate of lead, and changed every twenty-four hours, or oftener, according to the state of the suppuration.

Ulcerations of the neck of the uterus being, as we have already said, frequently accompanied with uterine catarrh, it happens that the mucosity coming from the orifice of the uterus falls, on account of its more declining position upon the posterior lip of the os tincæ, and covers the ulcerations that may be found there. When we desire to cauterise those ulcerations, as has been observed by M. Lisfranc, we only touch the mucosity; this must, therefore, be previously removed, which is sometimes easy by means of a charpie brush, or by a long pair of pincers, which I have caused to be made for the purpose; but, in some circumstances, these means being insufficient, I direct a charpie brush, steeped in the acidulated nitrate of mercury, upon the mucosity, and thus coagulate it. Removing it thus coagulated, by the aid of the pincers, I cauterise, with the greatest regularity, the ulcerations thus laid bare.

In upwards of sixty patients, in whom we have cauterised ulcerations seated upon the neck of the uterus, we have never had the least accident. Four or five patients at most have experienced a slightly burning sensation*.

The cauterisations have been repeated every six or eight days, care being taken not to apply them during the menstrual period. We have never yet practised more than ten in the same individual, and have thus dismissed, cured, women who might have been deemed incurable.

Uterine discharges that are transparent, and which constitute simple whites, have often disappeared, or have much diminished, when the ulcerations that existed upon the neck have been cured. Some uterine discharges, opaline and even purulent, have in like manner disappeared with the ulcerations of the neck; but in five cases the purulent discharges existed alone; and appearing to depend upon atonic ulcerations of the cavity of the neck, we have attempted dilute injections of the acidulous nitrate of mercury into this cavity, in the manner already indicated. Three of these discharges have been radically cured, two have only become transparent and less abundant.

The following is the process I employ:—a double-barrelled syringe contains in one of its parts the dilute acidulous nitrate of mercury †, and in the other, pure water. Its pipe, also double, is adaptable to a gum elastic catheter, open at its two extremities. The free extremity of this catheter, smeared with some greasy body, is introduced into the cavity of the neck of the uterus, into which about a teaspoonful of the dilute acidulous nitrate of mercury is then injected, allowed to remain for one minute, and then to be expelled by the injection of the water, without the syringe requiring to be displaced, or the instrument to be changed.

All the patients injected have experienced immediately afterwards, or only after the lapse of some hours, pains in the loins, and a little heat in the hypogastrium, which have been dissipated by seat baths. These unfavourable signs were calculated to frighten us at first, but have never been followed by serious symptoms.

Two patients have had five injections, the others three or four. These injections have only been made at eight days' distance from

* Since this M. Ricord informs me, that he has cauterised upwards of 300 women on the neck of the uterus, or os tincæ, with success, and without any serious consequences. I myself have seen him cauterise upwards of a hundred without any dangerous consequence. Care must however be taken to have the charpie brush free from drops that might fall upon the vagina, and do considerable injury by exciting unnecessary irritation.—A. T.

† One part by weight of acidulous nitrate of mercury to twelve by weight of pure water.

one another. The solution of acetate of lead has been successful with us in several cases of transparent uterine catarrh.

We here terminate a labour, doubtless very imperfect, but which we have been anxious to present to the learned Academy, which has done us the honour of listening to us, as an engagement entered into with it to communicate to it the result of all our observations, in order that its enlightened criticism may turn us from the path of error, if we are likely to fall into it, or that its approbation, when we shall have merited it, may reward us for our labour.

A TRANSLATION OF BARON ALIBERT ON DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

(Continued from page 208.)

SPECIES 4. — *Teigne Amiantacée*. — *Tinea Asbestina*.

This form has no crusts, but shining silvery scales, which by their concretion harden and unite the hair the whole length in parcels, and its silky and delicate appearance causes it to bear a striking resemblance to asbestos.

It is easily known at first sight, but as it is very rare, it is not astonishing it has escaped the observation of my predecessors; we must at least presume, that if some medical men have met with it, they have after a slight examination, confounded it with the furfuraceous scald head. It generally occupies the upper and fore-part of the head; it is particularly characterised by very small fine scales, of a silvery and mother-of-pearl appearance, which surrounding the hair, do not resemble amiss that thin and transparent pellicle with which the feathers of young birds are surrounded when they are first hatched, or rather that substance, called by naturalists, asbestos.

Such are the principal physical characteristics of the amianthous scald head. When the hair, thus hardened with this scaly matter, is cut with the scissors, the skin appears furrowed; it is red and inflamed, but much less so than in the forms before described: the itching is inconsiderable, as this teigne is almost always dry; it does

not emit any perceptible smell. The following case will serve to complete this description.

CASE 1. — Bard, aged 28, had a mother, who was afflicted with a disease similar to the one about to be described: in his infancy he had neither the croup nor crusta lactea. He had four brothers, three of whom enjoyed good health, the fourth, who was the youngest, experienced an analogous affection. Five years since he got the itch; he was attended by a quack, who rubbed him with a pomatum, of the composition of which he was ignorant; he was cured quickly enough, but since that period he has felt, at every change of season, an itching, more or less smart, principally about the knuckles; this state lasted some weeks. It is about fifteen months since he met with violent vexations, and was tormented by two passions, equally strong, love and jealousy. In the winter of 1805, on getting out of bed, he used to wash his head every morning with cold water, one day several pimples showed themselves on the crown, accompanied at intervals by tolerably smart itching. Every time he scratched he excoriated them, and caused a greyish humour to flow, which, by drying in the hair, was converted into scaly scabs, and, as these scabs came off, they were replaced by new ones; for thirty days the patient took Belloste's pills as well as a common purgative, notwithstanding the disease in question made rapid progress. This was his condition when we first saw him. The disease occupied all the upper part of his head, from the front to the back, and, transversely, it spread from one temple to the other. In some places were yellowish crusts, that there was some difficulty in pulling off, and you then perceived the ulcerated scalp. In the rest of the space, occupied by the disease, the hairs lay in their natural direction; they were glued together in such a manner as to form a sort of cap. From the basis of the hair there arose small flakes, of a silvery white,

more or less long, separated from each other by a kind of striæ. When these waves were taken off there were furrows more or less deep; the *tout ensemble* of the flakes, separated from the hairy skin, resembled the natural appearance of the asbestos (asbestinum), the resemblance was so striking that almost all the spectators were deceived by it. The patient was cured by a mixture of sulphur and cerate; it was necessary to continue this application for several months.

SPECIES 5.—*Teigne Muqueuse.*

This teigne has yellow crusts, which are easily detached from the scalp, furnishing a mucous matter, which hardens and glues the hair in lumps and layers. This disease does not confine itself entirely to the head, it sometimes extends to the forehead, face, and about the temples and ears.

It has been very inaccurately described by my predecessors, the greater part have confounded it with the milk rash, but it differs visibly in its exterior characteristics, and the great intensity of the symptoms which accompany it, in short, the affection, known under the name of *croûte lacteuse*, is generally only a mass of squamous or furfuraceous crusts, white, most often dry, rarely wet. It only attacks children; the mucous teigne, on the contrary, is so violent, on account of the symptoms it brings with it, that it is dangerous to allow it to proceed uncontrolled. It shows itself during the two first years of childhood, and I have seen it frequently where the milk has been bad, or combined with an imperfect and laborious dentition. I have also observed it in children born of scrofulous parents, or who were subject to other diseases of the lymphatic or cutaneous system. This affection, which I am now describing, is generally characterised by superficial ulcerations, which occupy more particularly the scalp of children, but it also extends to the forehead, temples, ears, and sometimes body, arms, and thighs, as I have remarked at the hospital of St. Louis. These ulcer-

ations are of a very sharp nature, furnish a mucous matter, which runs from all parts, and resembles spoilt honey; in some cases these ulcerations dry entirely, by coming in contact with the air, or through the influence of the heat, and form crusts of an ashy colour, or as yellow as wax, offering sometimes even a green shade. I have observed the origin of these ulcerations, and they begin in a very different manner: sometimes the pustules are large, sometimes small, sometimes they are sharp vesicles, which contain a transparent liquid of a yellowish white; sometimes there are abscesses, which occasion fever, and cause so painful a distension, that I have been obliged to open them in order to facilitate the outlet of the liquid they contain. The pustules or vesicles break spontaneously, or are broken by the child in scratching. The viscous liquid they contain turns to soft crusts of a yellow straw colour, often mixed with a reddish tint, but a new humour flows every moment from these same sources, we have even seen the nasal mucus flow in such abundance from the nasal holes, that the child's breath was quite oppressed by it. There are places in the head which do not show the particular ulcers we have already mentioned, but where the cellular structure swells and rises so greatly as to cause inequalities and bumps, more or less considerable. These swellings insensibly sink through the rupture of the neighbouring vesicles, or give place to different suppurations. Sometimes this cellular and cutaneous tumefaction arrives to such a degree of intensity, that the ears acquire double their size. It is then especially that a state of phlogosis, of redness, and extreme tension shows itself along the cheeks, and over almost all the face. Nothing can express the violence of the itching to which these children are a prey, when their heads are uncovered and exposed to the air it is still more violent. Then they toss their heads eagerly against their shoulders, and if their hands are free

they hasten to scratch themselves with an eagerness, which shows the delight they experience from it. Through the effect of this general irritation the greatest part of the head is deprived of hair; the naked skin is of a rose colour, but the inflammatory symptoms are less than in the forms already described. The texture of the skin is shining, because it is constantly damp, and often stained with a mucus of a caseous appearance. The smell it emits resembles sour milk. It is more or less offensive according to the degree of intensity of the symptoms. I have observed several changes in the manner of children during its different stages; when the crusts are dry, and ceased to be bathed with mucus, they are mournful, silent, uneasy, and look ill. On the contrary, when this excremental matter flows with abundance, when it waters and penetrates every part of the scalp, their faces are lively and their functions are perfectly regular. My general remarks will show the conclusions that must be drawn from this circumstance. I have, however, seen the mucous scald head make such advance and exhibit such serious symptoms, that children have fallen into a kind of consumption, have become very thin, their eyes hollow, &c.; in short, at the height, the debility induced by it gives occasion to the development of other diseases of a dangerous nature.

CASE I.—I had occasion to observe at the Hospital St. Louis, Joseph Buisseret, aged twenty months, who was afflicted with a mucous teigne; this affection showed itself at a time when his nurse had just undergone great troubles, her husband had been carried to prison, she was then seriously ill, and was even delirious, though this lasted but a short time; notwithstanding this unfortunate accident she continued to suckle the child till her milk was entirely exhausted; the child almost immediately had its head covered with yellow thick crusts, having no determined form,

wetted with a considerable quantity of very foetid ichorous matter, which flowed from small ulcers, with which the scalp was strewed; these crusts came off easily by the application of emollient lotions. The head was then red, bloody, and stripped of the epidermis. This child had an illness, caused by teething, and during this time the disease of the scalp entirely disappeared.

The description of the mucous scald head I have just drawn, and the observations which accompany it, ought, I think, to distinguish it from that slight affection, commonly known under the name of the *crusta lactea*. This indeed is only common to children at the breast, and does not last longer than the time of suckling. It is only characterised by slight furfuraceous white scales. The *T. muqueuse*, on the contrary, has extended crusts, yellow, ashy, or of a red brown colour, very firm, and covering the head like a cap. It excites an itching much more violent than the *crusta lactea*, and emits a more foetid humour. Another thing, in which the mucous scald head differs from the other species, is in its attacking less deeply the scalp, in appearing rarely beyond the age of four years, and in the ulcers being always wet, which appears to us completely to justify the denomination we have given it.

CASE OF TRAUMATIC TETANUS SUCCESSFULLY TREATED.

BY A. C. BALDWIN, M.D., OF GEORGIA.

On the 7th of January I was called to see a negro boy, aged about six years. On examination, I found he was labouring under tetanus. His body was bent back by the spasmodic contraction of the muscles, forming that variety of the disease called *opisthotonos*. A splinter in the foot was the only cause to which the origin of the affection could be attributed, and this had been removed on the day preceding my visit. The wound had suppurated, and on being opened the splinter had been discharged.

Aware of the great torpor of the bowels in tetanic affections, I determined on the exhibition of a cathartic as soon as possible, with the hope of securing all the advantage which could be derived from early purging, before administering the usual remedies employed in such cases. A combination of equal parts of the oil of turpentine and castor oil was accordingly directed in doses of a tablespoonful, frequently repeated. A blister was applied to the spine, and the foot was enveloped in a ley poultice. On the day following, I found that the blister had drawn well, and that the bowels had been freely evacuated; yet my patient was growing worse, and could swallow only with the greatest difficulty. To relieve pain and to produce relaxation, I directed a combination of equal parts of laudanum and antimonial wine to be taken in teaspoonful doses every one, two, or three hours, as the circumstances of the case might require. The more violent the pain, and the more formidable the spasm, the more frequently was the medicine to be exhibited, and *vice versâ*. To assist in fulfilling the same indications, a poultice of tobacco was prescribed, as an application to the blistered surface, with an express direction that it should be instantly removed if any of those untoward symptoms should occur which usually characterise the deleterious operation of this powerful article.

The opium and antimony thus combined, acting conjointly with the poultice of tobacco, seemed to control the disease, and from that circumstance were continued from day to day, and, with the exception of a little castor oil occasionally administered, were almost the only remedies employed in the management of the case during the time of its continuance. As soon as one blister would heal a second was applied on or near the same place, and the raw surface was dressed as before stated. In the preparation of the poultice which was employed, half a pint of boiling water was poured on an ounce of tobacco, and after a strong

infusion was formed a sufficient quantity of bread was added to give the proper consistence.

Although the progress of the disease was checked by the opium, antimony, and tobacco, yet entire relief was not immediately obtained, and the affection remained for some weeks stationary, during which time the patient was scarce able to move without renewing or increasing the spasm, and could swallow nothing but liquids, and those with considerable difficulty. It was between the third and fourth week when prospects of a recovery began to make their appearance. From that time the affection very gradually diminished, and he by degrees acquired the power to move, sit, and stand up, although it was six or seven weeks before he was able to walk any of consequence. At this time, rather more than two months since the commencement of the attack, he is walking about perfectly recovered, although considerable stiffness yet remains, and he has not acquired that power over the muscles which he possessed before the commencement of the disease.

Having witnessed the treatment of three or four cases of tetanus in which opium in large doses was the only remedy employed, every one of which terminated fatally, I took up the idea that the formidable complaint could not be controlled by this remedy alone, or that if the spasm yielded to its remedial influence, the injurious effects of such large doses of the article on the system more than counterbalanced the benefit thus acquired, and probably in a majority of cases contributed in bringing about a fatal termination. Influenced by that opinion, I determined, in the management of this case, to give it such doses as I thought would secure its anodyne and antispasmodic effects without producing those injurious consequences to which I have adverted; and at the same time to combine with it such remedies as would probably assist in fulfilling the indications desired. Whether my opinion was right or

wrong is left for others to determine. The result, at all events, of the case in which my practical views were enforced was favourable, and would seem to justify the practice. The union of the opium and the antimony seemed to have this good effect; the combination thus formed was less heating than the laudanum would have been if given alone, and by its relaxing influence acted on the skin as a diaphoretic. Neither nausea, nor vomiting, nor any other unpleasant effect resulted from the application of the tobacco. On the contrary relief was always experienced from its operation, whether employed alone or in combination with the remedies already enumerated.—*Amer. Jour. Med. Sc.*

MEDICAL RETIRING FUND.

Proceedings of the Temporary Committee of Management of the Medical Retiring Fund, Bengal Establishment.

THE Temporary Committee of Management of the Medical Retiring Fund held their seventh meeting at the house of the secretary to the Medical Board on Tuesday evening, the 2nd inst; Mr. Surgeon Corbyn in the chair.

The report of the proceedings of the last meeting having been confirmed, the revised plan of the regulations of the fund by the committee was next read; and on the motion of Mr. Corbyn, seconded by Mr. Egerton, it was resolved unanimously,—

1. "That the revised plan of the regulations of the fund be printed and circulated for the opinion or approval of the respective members of the profession."

Letters from the following gentlemen, stating their assent (as subscribers) to the fund were now read: Surgeons F. Corbyn, O. Wray, J. Grant, J. Clarke; Assistant Surgeons B. Burt, J. Magrath, R. B. Duncan, D. Woodburn, J. Corbet, A. Campbell, A. Colquhoun, D. Russell; also from Assistant Surgeons H. Clark, A. Campbell, transmitting their votes

in favour of Mr. G. Ballard to be permanent Secretary to the Fund; from Assistant Surgeon W. A. Green, for Mr. J. Young; from Surgeons W. S. Charters, J. Clarke, and Assistant Surgeon J. Colvin, for G. J. Gordon; from Assistant Surgeons G. J. Berwick, D. Woodburn, for Mr. J. Hutchinson; from Assistant Surgeons A. Colquhoun, G. Turnbull, for Mr. Pearson; and from Surgeons J. J. Paterson, F. Corbyn, J. Grant, Assistant Surgeons, R. B. Francis, B. Wilson, J. Fender, for Mr. H. S. Mercer: likewise from Surgeon J. Henderson, and Assistant Surgeon J. Corbet, transmitting their subscriptions to the Fund, and from Superintending Surgeon T. Smith of the Allahabad division of the army, and Surgeon J. M. Todd; the latter proposing alterations in some parts of the regulations of the Fund.

Dr. Charters, in giving his vote for the appointment of Secretary to the Medical Fund, says, that he thinks it would be advisable that the situation should be given to a mercantile gentleman; he conceives it to be for the benefit of the Fund that the Secretary should be enabled to devote the greater part of his time to the performance of its duties; the time of a medical officer holding an appointment at the Presidency cannot, from the nature of his avocation, be at all periods disposable, nor can he be supposed to be so conversant in the management of accounts as a person accustomed to, and educated for, a mercantile life. He gives his vote for Mr. G. J. Gordon, but if it should be decided by a majority of the subscribers that a medical gentleman shall be secretary, he in that case votes for Mr. Mercer.

Mr. John Grant, in stating his wish to become a subscriber to the Fund, observes, that with reference to the situation of Secretary to the Institution he has much pleasure in offering his vote to Mr. Mercer, who, for the reasons he states, he considers has the best claims to that appointment of any of the candidates who have offered.

Mr. Smith, in his communication, states, that in reply to the circular letter of the 16th ult. he begs to inform the Committee that he does not intend to become a subscriber to the Medical Retiring Fund on the plan at present proposed, to which he states his objections. Should, however, any other plan doing away with those objections hereafter be proposed, he shall be happy to become a subscriber; and in the event of a Permanent Secretary being decided upon, which he should consider indispensable, and whose salary of 300 rupees per mensem he approves of, he should in that case give his vote in favour of Mr. James Young, and which, from the correspondence he has had, he is warranted in saying all the other officers in the Allahabad division would also do, who might become subscribers to this or any other subsequent plan of a fund which might be proposed.

Mr. Bramley here stated, that Mr. Twining had no intention of joining the Retiring Fund Society, and was not therefore eligible to be chosen one of the Committee.

The following resolutions were next proposed by Mr. Mercer, to be added to the plan of the Fund, which were seconded by Mr. Corbyn and carried:

2. "That all applications for an Annuity from the Fund shall be accompanied by a certificate of the age of the individual verified on oath before a magistrate, or declaration on honour."

3. "That all applications for the payment of an Annuity in India or in England shall be made by the person entitled thereto either in person or by some one authorised by him, accompanied by a certificate verified on oath before a magistrate, that the person entitled to the annuity was alive at the time to which he claims payment."

4. "That the Annuity shall be regularly paid half-yearly, either in India or England, wherever the party entitled to it may choose to receive it, on sanction being obtained from the Hon. the Court of Directors."

Proposed by Mr. Hutchinson, seconded by Mr. Corbyn, and carried—

5. "That any subscriber, subsequently to the establishment of the Fund, giving up promotion while holding the rank of surgeon, shall not prejudice his right to the annuity, provided he continue to pay his subscriptions according to the rank he would have held had he not given up promotion."

Proposed by Mr. Bramley, seconded by Mr. Mercer, and carried—

6. "That the thanks of the Committee be given to the Chairman, Mr. Corbyn, for the able manner in which he has fulfilled the duties required of him during the term of the Temporary Committee's management."

Proposed by Mr. Wood, seconded by Mr. Pearson, and carried—

7. "That the thanks of the Committee be given to our Secretary, Mr. Mercer, for the able manner in which he has conducted the laborious duties required of him during the continuance of the Temporary Committee's management."

Resolved—That a quarterly meeting of the subscribers to the Medical Retiring Fund shall be called for Monday evening next, the 8th inst., at eight o'clock, to be held at the Asiatic Society's apartments.

H. S. MERCER, Sec.

Calcutta, 4th April, 1833.

Reviews.

A Report of the Method and Results of the Treatment for the Malignant Cholera. By JOSEPH AYRE, M.D.

It is a generally received opinion, that a man with a bad name is better shunned than sought, but we shall not be so uncharitable as to judge Dr. Ayre by the ungrammatical, and therefore bad title of his book. Its contents and statements, for the accuracy of which he considers himself as standing pledged, will we hope be found less objectionable. After speaking of the symptoms and remote causes of the disease, the author recapitulates his opinions, which we

shall take the liberty of condensing for the benefit of our readers. He considers,

"1st. That the cholera consists in an interruption, and in some cases of a complete cessation, of the secretion of bile, thence inducing venous congestion of the liver and other abdominal viscera, and of the vertebral veins.

"2ndly. That from the above there results a suppression of urine and congestion in the thoracic vessels, causing spasm, collapse, loss of heat of surface, &c.

"3rdly. That there then follows an interruption in those chemical changes of the blood necessary to the expulsion of its excrementitious (!) principles.

"4thly. That an indirect stimulus to the abdominal arteries is given by the congested veins morbidly irritating the capillary system of the implicated organs.

"5thly. That if the natural powers of the system be insufficient to overcome this congestion, the exhalant extremities of the stomach and bowels receive an increased current of blood, and a profuse muco-serous secretion is the consequence.

"6thly. That in some cases where the congestion terminates spontaneously or favourably, it is by a renewed secretion of bile.

"7thly. That where this secretion does not occur, and the congestion does not destroy the patient, increased action of the capillaries of the stomach and bowels ensues, and a febrile state ensues, differing only in intensity from common bilious fever.

"8thly. That the above forms a remedy to the congestion whereby the action of the kidneys is restored, and the alvine discharges assume a healthier appearance.

"9thly. That the remote cause of the foregoing conditions consists in a morbid irritation of the stomach and bowels, caused by noxious malaria and unwholesome ingesta, the malaria being variously modified, &c."—pp. 68, 71.

The above constitutes a candid epitome of Dr. Ayre's "Method;" our space will not allow us, nor do we feel called upon, to notice it more particularly, presenting as it does no new features of the disease in question, and leaving nothing unsaid that had not been said before. After reading the above, our readers will be fully prepared to digest "the small and frequently repeated doses of calomel," in the exhibition of which our author seems to take most unequivocal and special delight, and we are bound to add, with no little justice or slight degree of success, if

we may judge from the numerous well-authenticated cases cured by this plan of treatment which this volume records. If every method of treatment in cholera had been as well arranged, condensed, and recorded, as the one followed by Dr. Ayre, we should not have heard of so many "thousand and one" remedies for the disease, nor would the public and the profession have been deluded by so many catch-penny pamphlets on the same subjects.

Observations on Injuries and Diseases of the Rectum. By HERBERT MAYO, F.R.S., Surgeon to the Middlesex Hospital.

(Second Notice.)

In speaking of fistula ani, Mr. Mayo considers that it should be separately studied in its two stages, first, as an abscess, secondly, as a permanent sinus.

"Abscesses near the rectum admit of a practical distinction into two kinds: either they are small and superficial, which is the character of those that lead to fistula, or they are deep-seated, when they often contain large accumulations of matter, but rarely produce the secondary complaint.

"The frequent occurrence of abscess near the rectum results from the dependent situation of the part, and from the quantity of loose adipose and cellular tissue with which it is surrounded. From these causes the blood in the hæmorrhoidal veins presses heavily on the capillary circulation; and inflammation and abscess in the part ensue, upon the same principle that inflammation and ulceration of the integuments of the leg are produced by varix. Whatever tends to diminish the quantity and firmness of the adipose tissue at the lower part of the pelvis, lessens in the same degree the lateral pressure upon the veins, and encourages congestion in them: causes which produce this effect lead, therefore, to abscess near the rectum. I have frequently seen large abscesses around the rectum, in patients in whom the complaint has evidently been brought on by hard work and insufficient nourishment; and it is well known how liable small and superficial abscesses are to occur in those who are extenuated through pulmonary disease.

"The formation of deep-seated abscess near the rectum is to be suspected when the patient experiences aching and throbbing pain in the part, often not constant,

but recurring at intervals, and frequently with a spasmodic character, the pain being aggravated on the passage of the feces, and the complaint attended with symptomatic fever. The abscess often does not declare itself by any external fulness or prominence, and its existence can only be ascertained through an examination of the rectum, when, at some part which is more tender than the rest of the mucous surface, a fulness and fluctuation, if the abscess is matured, are felt.

“The most important practical rule respecting deep-seated abscesses near the rectum is, that they should be opened at an early period. The abscess left to itself is slow in making its way to the surface, and before it spontaneously breaks, an immense accumulation of matter will have been formed. While this process is going on, the patient suffers under increasing pain and irritative fever; and as the complaint generally affects those who are of a debilitated constitution, the patient is in danger of sinking before the natural relief of the abscess has taken place.”—pp. 102, 105.

Complication of fistula ani with urinary fistula.

“When this exists, the plan to be followed is first to close the communication with the urethra, which may often be accomplished through regulated diet and medicine, without the use of instruments, unless there is stricture of the urinary canal. When the communication between the urinary canal and the sinuses has closed, which is known by the urine ceasing to flow through them, the cure is completed by the common operation for fistula ani.”

The chapters on constipation, and stricture and cancer of the rectum, contain many valuable practical remarks; our limits will not, however, allow of our making further extracts; the quotations we have made will sufficiently show our readers the practical value and importance we attach to a work like the present. The class of diseases treated of, though not perhaps extensive, is yet one of which every practitioner meets with numerous instances, frequently both obstinate in their symptoms and complex in their treatment, and in the absence of higher professional opinion, we cannot recommend a work containing a greater share of practical information on the injuries and diseases of the rectum than the one we have now noticed.

THE

London Medical & Surgical Journal

Saturday, September 21, 1833.

THE GENERAL DISPENSARY, ALDERSGATE STREET.—DISPENSARIES IN GENERAL.

WE are highly gratified to think that the suggestions to the profession, inserted in our last, have been fully acted upon, and that the physicians and surgeons of this metropolis, with one solitary exception, have declined to offer themselves for offices under the vote-making and bribery-electing Governors of the above Institution. These individuals will now see that their collision with their late medical officers was bad policy; and that their money-making speculation will turn out a complete failure. They have learned, perhaps, that the medical officers of a dispensary are the best judges of professional matters, and of the best means of securing the most efficient aid for the sick poor. They have shown themselves, like all who venture beyond the depth of their knowledge, extremely ridiculous; in attempting to interfere in a matter which they did not understand! They determined that the length of a man's purse, and not his scientific knowledge and experience, was the best qualification for the difficult and responsible office of treating the most fatal diseases. The most eminent members of our profession have long deplored this system, and, actuated by pure philanthropy, have invariably endeavoured

to correct it. In many dispensaries they have effected their object; and we rejoice to think that the Aldersgate-street affair is a fatal blow to the evil which they have so zealously combated. It will be a lesson to dispensary governors throughout the kingdom which they will not speedily forget. It will teach them to respect professional services, if they cannot appreciate their value, and to look upon medical officers as something more than menials. It was time that a stop was put to the impertinence and insolence of these guinea-subscribers, who assume more consequence and airs than the proudest nobleman in the land. These are the persons who, when they are admitted on committees, have the rudeness to designate the medical officers "servants of the charity." They expect the most punctual attendance on the part of such officers; and bring forward charges of neglect if *their* recommendation has not been immediately attended to; and they are so exceedingly wise and considerate, that if they give a letter for admission to some servant, workman, or poor relation, at any hour of the day, they expect a physician or surgeon to turn his back on his private patients, break his appointments and arrangements, and attend instantly to their mandate. This is the conduct of the generality of subscribers in all dispensaries.

But these persons usually exclaim, "Why do medical men give their services unless for their own advantage?" In answer, we reply, that though many of our profession con-

sider it a personal advantage, (which we, however, deny,) that is no reason they should be wantonly and grossly insulted by those who are, in all respects, inferior to them. They afford inestimable advantages to the poor; they restore the father, the mother, and the child, to health; they confer the greatest benefits on the labouring classes, without any reward except the consciousness of doing good; they give their time, which is as valuable to them as that of a tradesman's; and they are to be called to account by some governor who devotes an hour once a month to the affairs of the institution!

But it is urged "they have self-interest in view, they wish to become known." We shall grant this for the sake of argument; but why should they be treated as servants? Where is the man who is not influenced to some extent by self-interest? We must, however, deny that all medical men attend dispensaries for the selfish purpose of becoming known; and we can adduce undeniable proof, from the late officers of the institution, which gave rise to these remarks. We should ask our opponents, how Dr. Clutterbuck and Dr. Lambe, both eminent physicians, and as well known as they possibly can be, attended the General Dispensary, up to the hour of their resignation, for the purpose of acquiring fame by the institution? No, they attended from motives of genuine philanthropy. It must be admitted, however, that the junior members of the profession are generally anxious to obtain dispensaries to become known,

and offer their services gratuitously. This we have long considered a great mistake. We are convinced that a physician or surgeon, who thoroughly understands his profession, and sees the poor at his own residence, will as speedily acquire reputation, while he will avoid the contumely and insolence of dispensary governors. But it will be urged, that he loses the opportunity of obtaining an acquaintance with respectable governors. This is true; but we can assure him, it is reputation only that will obtain for him one patient among them. We know a physician, who is attached to one of the most respectable and crowded dispensaries in this city, and who has frequently declared, that though he had been indefatigable in his attendance during the last twelve years, he never received one fee by the institution. Governors of dispensaries, like all other individuals, have their own medical attendants, and they will seldom change them without just grounds.

But we should like to know the reason that medical practitioners are the only class in society which is expected to act gratuitously. We should wish to be informed why the great parish of Mary-le-Bone, containing three-fourths of the mobility and most affluent individuals in the metropolis, expect the medical officers of their infirmary and dispensary to give their services gratuitously? The generality of those connected with dispensaries are remunerated except the medical man. This system must be altered—times are changed, and we must change with them (*tempora*

mutantur, &c). We trust the day is at hand when the legislature, in reforming the practice of profession in England, will see the expediency of legislating for this section of the empire, in the same way as they have done for Ireland, where all county hospital and dispensary medical officers are remunerated for their services.

We might dilate upon this topic, but we must have done. We might show the paltry pittances which are allowed parish surgeons, both in this metropolis and in the country, who in general do not receive one half-penny a visit for their attendance, which, in the latter, may be ten or twelve miles distant. Here again every other parish officer is remunerated. But the medical faculty is expected to act gratuitously.

Since the preceding was in type we have been informed that there is to be a public meeting of the profession, to consider the question lately in dispute, between the Governors and Medical Officers of the General Dispensary, Aldersgate-street.

BEAUTIES OF THE ADMINISTRATION OF JUSTICE.

It is not our desire to occupy the attention of our readers with the private concerns of this journal. But we cannot forbear expressing our satisfaction, that tardy justice is at length about to be done to the merits of John Minter Hart and his associates, that well-known gentleman, by whose kind aid as a special juror and affidavit-man, Dr. Ramadge was rewarded at our expense, for his

support and defence of Mr. St. John Long, and we deprived of nearly a thousand pounds. The account of this transaction will be found in Vol. I. p. 710, and Vol. II. p. 532, of this journal, and well deserves the consideration of the honest reforming lawyer. It is sufficient for our purposes to state, that Minter Hart, gentleman attorney, but struck off the roll, aided by three of his company, denied, it is needless to say on oath, that which was sworn to by Mr. Holmes and Mr. Hooper, two very eminent surgeons, whom to name is enough.

Nos numerus sumus, or the greater number of swearers carried the day, a new trial was refused, and we had to pay, by means of Minter Hart, 400*l.* for that grave offence against Dr. Ramadge, which cost the editor of the *Lancet*, who was the original offender, one farthing the day before, and which was valued the morning of the trial by the doctor's acute legal advisers, at forty shillings and costs. The public document which has led to these remarks is the following, which has appeared in all the newspapers, and is placarded throughout the city.

ONE HUNDRED GUINEAS REWARD.—Whereas on Monday last a True Bill, for fraudulently conspiring to obtain 5,000*l.* worth of Acceptances, for which the Acceptor had received no consideration whatever, was found against the undermentioned persons, namely,—

John Minter Hart, otherwise John Moreton, of 52, George-street, Hampstead-road, and Mornington-crescent, and recently struck off the roll of attorneys.

James Archdeacon Richardson, late of Loughborough-road, Brixton-hill, but now in custody;

Henry Richardson, of 7, Clement's Inn;

Henry Palmer, of 7, Hertford-street, May-fair, formerly a clerk to John Minter Hart, but now in custody;

Peter Clissold, residence at present unknown;

Thomas Wilson, otherwise Thomas Wilson Richardson, of 11, Portland-terrace, Regent's-park, St. John's-wood, London; William Bond, of 35, University-street, Bedford-square; and

Jane Tucker, late of the same place, widow;

And proceedings having been taken against several of the above-named parties, who have absconded, for **FELONY**;

Notice is hereby given, that the above reward will be paid to any person or persons who will give such information to Messrs. Henson, Staniland, and Long, No. 9, Bouverie-street, Fleet-street, London; to Mr. Burnaby, Chief Clerk at the Public Office, Bow-street, London; or to Mr. Mallet, Chief Clerk at the Public Office, Hatton-garden, London, as shall lead to the apprehension and conviction of the said several parties for the offences.

And the Public, Bankers, Merchants, Bill-brokers, &c. are hereby cautioned that the said several Acceptances, bearing date the 2nd day of August last, and filled up for 500*l.* each, payable at two months after date, to the order of the respective drawers, purporting to be P. Clissold, Thomas Wilson, and Henry Leigh Hunt, having been fraudulently obtained from the Acceptor, without any consideration whatever, will not be paid when due.

London, September 12, 1833.

CAUTION.—Whereas, Three Promissory Notes, each for 115*l.*, dated respectively the 8th May, 1833, severally drawn by Richard Lee, payable to his own order, at nine, twelve, and fifteen months after date, and indorsed by him, have been improperly, and without consideration, put in circulation, and were in July last offered for discount to John Minter Hart, of No. 19, Mornington-crescent, Hampstead-road. This is to give notice, that the said Promissory Notes, and each of them, will be resisted payment, and are hereby required to be given up to Mr. Bebb, 20, Great Marlborough-street, Regent-street, solicitor to the said Richard Lee.

ST. JOHN LONG.

THIS famous person lately called on the editor of the *Limerick Chronicle* and told him that Dr. Townsend was commissioned by the Dublin College of Physicians to propose to him to treat six consumptive patients selected by them. This piece of intelligence

ran the rounds of the Irish newspapers, and we were about to comment on its improbability, when we read a contradiction to it by Dr. Fergusson, President of the College, and a declaration by the above editor that he had the intelligence from the empiric himself. This fib was a good and cheap advertisement for the quack, during his itinerary in search of Irish consumptives, as his occupation is gone in this country.

ADVANTAGES AT KING'S COLLEGE.

WE have been favoured this week with an inspection of King's College. This very handsome building is perhaps the most beautiful of Sir Robert Smirke's classical designs. The entrance hall is extremely noble; a flight of steps with massive stone balustrades, leads on each side of it to a corridor, which traverses the whole length of the building, and is upwards of three hundred feet in extent. In the centre of the corridor fronting the grand entrance is the entrance into the chapel; the suite of rooms on either side of which are as yet unappropriated; the opposite suites of rooms which look towards Somerset House, are the one for the general library, the other for the anatomical museum. The general library is as yet very limited, but several valuable donations of books have already been made to it. The anatomical museum is of great value. It contains altogether between three and four thousand specimens. About two thousand are to be seen in the principal room. The preparations are excellently preserved. They are for the most part pathological, but there are a few of remarkable beauty illustrating natural structure. The most original series of these displays the structure of the brain. But the growth of bone, the structure of the heart and blood vessels, and of the organs of generation are likewise

well illustrated. Of the pathological series, those of the diseases of bones, of the joints, of the alimentary canal, of the lungs and blood vessels are the richest. A dilated œsophagus, a varicose artery, a polypus of the epiglottis, and a series of preparations of the spinal marrow, are the rare specimens in the collection. The diseases of the bladder and urethra are likewise very richly exemplified. The nucleus of the museum was Mr. Mayo's; it has been enlarged under his direction, and with his assistance, by the present curator Mr. Cane; Mr. Partridge, the demonstrator of anatomy, has likewise contributed several beautiful preparations. The wax models representing morbid structure are perhaps the best in London.

We visited next the general theatre; it is well lighted, and adapted to hearing. Among others Professor Green delivers his surgical lectures in this theatre.

The chemical lecture room is separate from this; the laboratory, which has every requisite that can be imagined, is placed below it.

The anatomical theatre and the dissecting rooms, are detached from the main building, and situated immediately on the bank of the river. The accommodations in them of every description are capital, and the whole establishment for the medical school, which alone we had time to inspect, formed a strange contrast to our recollections of the dark, dingy, and inconvenient rooms, which we remember in our youth, as the unwholesome nurseries of professional science.

The hours at which the lectures are delivered are from eight in the morning till twelve. At ten prayers are read in the chapel; the daily service occupies ten minutes; the students attend with very creditable regularity. No lecture is delivered between twelve and half-past two; this interval being left for dissection or hospital attendance. The anatomical lecture is given at half-past two; the surgical lecture at eight in

the evening. There is an excellent medical library and reading room, in which the student may pursue his studies in the intervals of the lectures which he attends; refreshments may be had at a cheap rate, when desired, in the college.

The terms of attendance for occasional students are much the same as elsewhere. For those who pursue their whole course of study at the College they are lower, being 50*l.* paid at once, or 25*l.* paid in October, and 25*l.* in January. The King's College medical students have permission to wear the academical cap and gown of the literary students.

The deficiency which some would find fault with in this school, is the want of a hospital adjoining it. It cannot indeed be said that a hospital is not attached to it; for three of the professors are officers of the Middlesex Hospital, and one is surgeon of St. Thomas's. For our own parts, we consider the immediate contiguity of an hospital of little consequence. It is quite as well, when the student has had four hours' hard work in attending lectures, that he should have a walk of a quarter of an hour or twenty minutes, to shake down his ideas, and to recruit and refresh his mind and body, before he plunges into the close wards of an hospital. The walk to the Middlesex Hospital, which is the nearest, is a little over a mile. Several of the students now attend St. George's and the Westminster Hospitals, and others St. Thomas's and St. Bartholomew's. By this means the body of practical knowledge among the King's College students is not the narrow result of studies confined to one school, but is improved and enlarged by information borrowed from every source.

The anatomical museum is open to the public every day but Wednesday, from twelve till three; and strangers who wish to visit the other departments of the College, meet with civility and attention every where.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Excision of fungus hæmatodes in the leg, by Mr. Lawrence, with clinical remarks.—On Saturday, Sept. 14th, a most interesting and important operation was performed in this hospital by Mr. Lawrence, viz. the excision of fungus hæmatodes. The patient, whose case has been given in full in No. 81 of the Journal, has been in the hospital many weeks. During that period the fungus has been gradually increasing in size, occasioning the greatest torment to the patient, and rendering his existence truly miserable. Mr. Lawrence proposed amputation of the leg several weeks ago, but the patient obstinately refused to allow the operation. Mr. L. and his colleagues constantly represented to him the necessity of amputation, but no entreaties could prevail on him to change his mind. After much deliberation and consultation with the other surgeons of the hospital, Mr. L. proposed, as a last resource, to excise the fungus and scrape away the periosteum beneath it. To this the patient willingly consented. Mr. L. accordingly last Saturday proceeded to perform this *experimental* operation.

The first step was the application of the tourniquet a little above the knee. Mr. L. then with a small knife commenced an incision above and continuing it in a semicircular direction brought it down to the bottom of the fungus. He then made a similar incision on the other side of the fungus, and proceeded with a still smaller knife to dissect out the fungus from its roots. Great hæmorrhage ensued on the first incisions being made, and three or four arteries were taken up. Mr. L. having now entirely excised the fungus, proceeded to remove a large portion of the anterior surface of the tibia, and found it necessary to cut down even into the medullary canal of the bone. This part of the operation occupied a long time,

during which the patient seemed to suffer intense agony, as the bone was evidently endowed with a morbid and exquisite sensibility. The wound being washed, some lint was gently placed over it without any adhesive plaster, and the patient was carried to bed after being about forty minutes on the table.

When the operation was concluded Mr. Lawrence delivered the following remarks.

"I have performed this operation, gentlemen, with a very unwilling heart, nor is it an operation which I should have ever performed were it not that the patient absolutely refused to allow amputation. I told him candidly my opinion as to the chances of this operation; I expressed great doubts of its success, and assured him of the very great probability of the reproduction of the disease. I moreover mentioned to him, that even if the leg did heal, and he was sent out of the hospital cured of the disease, still that a wooden leg would be much more serviceable to him than the one which he would have after the operation. He would not, however, submit to amputation. I then consulted with my colleagues, and we came to the determination of giving him the only chance left, viz. the excision of the fungus, and I am now sorry, on the poor fellow's account, to say that the operation has been most unfavourable. Contrary to my anticipations, which led me to believe that the periosteum only, or at most the very exterior surface of the body of the tibia, was diseased, I find that the entire anterior portion and medullary canal are intimately connected with the disease. I have been obliged to remove a large portion of bone, and the tibia in that part is now a mere shell, confirming my prognosis that even if the leg heals it will be of very little use to him. In several cases of fungus hæmatodes, of which preparations have been preserved in the museum, I find the periosteum only to be affected while the body of the bone remains quite sound. It was

this consideration which chiefly induced me to undertake this operation. Time will show us what may be its results, I cannot, however, help forming an unfavourable prognosis from all the circumstances which I have observed since the patient has been laid on the table. I send you round, gentlemen, the fungus which I have excised. It is highly vascular, has occasioned great pain to the patient, and a thin ichorous discharge has flowed from it during the last several weeks."

We shall not fail to make our readers acquainted with the results of this highly interesting operation.

Fracture of the radius.—In a case of fracture of the lower part of the radius, just admitted, Mr. Stanley said it was of the last importance to place this fracture in the proper position, as if the position was not cautiously regarded deformity was the certain consequence. The position should be in an inward and downward direction. Mr. Stanley particularly demonstrated the position in which such a fracture should be kept.

ST. GEORGE'S HOSPITAL.

Excision of a malignant Tumour of the Thigh.—On Thursday, Sept. 12th, a stout athletic man, æt. 60, was placed on the operating table with a large tumour of a malignant character, situated on his right thigh a little below Poupart's ligament. Mr. Walker, assisted by Messrs. Keate, Hawkins, Babington, and the house surgeons, proceeded to excise the tumour. Having first made a very deep incision all round the tumour, he detached its lower surface, and in a few moments entirely removed it. A few arteries were tied, and the edges of the wound approximated by means of slips of adhesive plaster. The patient was then conveyed to bed.

The tumour, on examination, proved somewhat fungoid in its structure,

but only one cyst was discovered in it. It was perfectly gelatinous, and contained a considerable quantity of thick viscid blood.

Fracture of the base of the Skull.—A strong athletic man, æt. 60, a groom by occupation, was conveyed to the hospital, about a fortnight ago, in a state of insensibility under the following accident. While in the act of cleaning his horse, the animal suddenly became restive, and jumping upon him, threw him down with great violence on the pavement. There was copious hæmorrhage from the right ear and nose. On being brought to the hospital he was bled, and leeches applied to the back of the head. The entire of one side of his body became paralysed. Notwithstanding the shock which the frame underwent, and the violence done to the brain, the patient lingered on till the 15th of September, on which day (the tenth after the accident) he died.

On a *post mortem* examination, it appeared that there was a fracture running along the entire base of the skull. There was also a fracture of the orbit of the eye running in a transverse direction to the other fracture. A great quantity of blood and pus was found in the brain.

Polypus of the Nose.—On Monday last Mr. Keate extirpated a polypus of the right nostril in a young woman æt. 19. Having introduced a forceps up the nostril, he obtained a firm grasp of the polypus. He then withdrew the forceps bringing along with it the polypus. There was some trifling hæmorrhage. A sponge immersed in water was then applied to the nose.

Stricture of the Urethra.—In a case of stricture of the urethra, Mr. Babington is using injections composed of two drops of nitric acid to one ounce of water. This treatment has already produced good effects.

French Hospital Reports.

HÔTEL DIEU.

Imperforation of the Vagina.—A young woman of sanguineous temperament, aged 24, was admitted under the care of M. Dupuytren, for a tumour of the abdomen, which she believed to arise from cessation of the menstrual discharge. After an attentive examination of the organs of generation, it was discovered that the vagina was so completely obliterated, that it was with difficulty any trace of its orifice could be discovered, and that the womb was as enlarged as in the sixth month of utero-gestation: after being interrogated as to the cause of this affection, she referred it to having been violated some time previously. The pain of the abdomen extended to the loins and thighs, and she complained of extreme agitation and want of sleep. Bleedings, leeches, baths, fomentations, antispasmodic and narcotic medicines, with emollient drinks, were administered without relief.

The patient's situation now became very precarious, and on making a second examination it was resolved to employ a method, which however doubtful, was better than abandoning her to a certain death.

The orifice of the vagina was entirely effaced by the adhesion of the vulva from the meatus urinarius to the perineum, and fibrous bands of adhesion were here seen to cross the parts; the clitoris and meatus urinarius were the only external sexual parts in their normal state. The position of the tumour was discovered by the finger being introduced into the rectum; pressure was applied over the hypogastric tumour, which brought it under the finger placed in the vagina. An incision was then made over the hard tumour, and an offensive black fluid was immediately discharged; the patient was very carefully returned to bed, and no dressing was placed over the wound. During the ensuing night the dis-

charge was considerable, and on the following morning the tumour was so small that it required pressure to discover it, and in the course of time the effusion was only mucous in its nature. The patient was recommended to introduce a dilating body into the wound to keep it open, and by this means she was completely cured. The occurrence of the menstrual periods afterwards was sometimes indicated by abdominal pains, headach, and oppression, which soon yielded to the use of pediluvia and antispasmodics.

HÔPITAL DE LA PITIE.

Typhus Fever.—A mason, aged 30, was admitted into La Pitié, having suffered from fever for fifteen days. Being of a strong constitution, he had always enjoyed good health. On the day after his admission he was lying on his back in a state of extreme prostration. Intense headach; stupor; eyelids closed; eyes sensible to light; tongue dry, and covered with a brown fur; thirst; want of appetite; no nausea or vomiting; bowels have not acted for some hours; pulse 56, irregular; surface dry and slightly warm; respiration 56; slight cough; no expectoration; pulmonary sound normal; posterior respiration accompanied with a *râle sibilant*. He was ordered decoction of quinquina in half glass doses, gummy potion, with eight grains of sulphate of quinine, and half a lavement, with fifteen grains of sulphate of quinine, with sinapisms to the feet, &c. On the following day, the cephalalgia was still present, but less intensely painful. Sleep short and broken; tongue moister; pulse 68; respiration 32. He had asked for food. The lavement had returned shortly after being administered; no evacuations; bowels indolent. Ordered gummy potion, with eight grains of sulphate of quinine; two basins of broth. The next day the sleep had been tranquil; tongue moist and cleaner; no evacuations or pains in the stomach; pulse 60, respiration

36; he looks more cheerful, and the prostration of system is less. Ordered twelve grains of sulphate of quinine every five hours; emollient lavement.

On the following day no headach; pulse 58, respiration 32, breathing healthy; cough with mucous expectoration; copious evacuation after the lavement. Ordered gummy potion, with six grains of sulphate of quinine.

The next day all traces of weakness had left him; pulse 60, and regular; respiration 28; no increase of cough; appetite good.

From this moment he became convalescent, and in the course of a week he left the hospital quite well.

BOOKS.

On some Points connected with the Anatomy and Surgery of Inguinal and Femoral Herniæ; being the substance of the Lectures delivered in the Theatre of the Royal College of Surgeons, Feb. 1831. By G. J. GUTHRIE, F.R.S., President of the Royal College of Surgeons, &c. &c. 4to. Four Plates. London: Burgess and Hill.

A Compendious History of the Small Pox. By H. GEORGE, Surgeon. 8vo. pp. 112. Churchill.

Principles and Practice of Obstetric Medicine. By DAVID D. DAVIS, M.D. &c. &c. Part XXIII. Taylor.

CORRESPONDENTS.

A Student must enter to the lectures in October. The portions of Celsus are the first and third books, and of Gregory the first ten chapters.

Riverius.—The lectures must be attended during two winter sessions, commencing in October and terminating in May. The student may enter to an hospital or dispensary after the first three months' attendance on lectures, but most persons enter to these institutions at the commencement of the summer. Our correspondent must remain at least two winters and one summer in London.

C. D. M. may be a very respectable gentleman in his own opinion but not in ours.

* * * Our next number will contain a full and explicit statement of the various schools of medicine and surgery for the ensuing session.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE I.VI., DELIVERED FEB. 21, 1833.

GENTLEMEN,—From the consideration of the diagnosis of aneurism in the circumscribed and diffused forms, I proceed to make a few observations on the *causes* of this disease. If we except those cases which arise from wounds, or from the injury of a considerable artery by the sharp point of a fracture, it seldom happens that we can ascribe an aneurism to external violence. Thus, if the knee-joint be extended in the greatest degree possible, and with the utmost force, the popliteal artery will not be torn and aneurism produced, unless the coats of that vessel happen to be already in a diseased condition. You will often find patients ascribing aneurisms to sprains and great efforts; but if such tumours should really have arisen from the causes referred to, a diseased state of the arteries affected must have preceded the circumstances leading immediately to their dilatation or rupture. It has been ascertained by experiment, that such an extension of the leg as would burst the popliteal artery, would first rupture the ligaments of the knee-joint. I may say, therefore, that those writers who have ascribed aneurism of the popliteal artery to external violence, appear to have been in error; at all events, such a case would not happen without some previous disease of the coats of the vessel.

There are, however, certain circumstances, which you may regard as *predisposing causes* of aneurism; and you may view in this light, first, the large size of an artery, and secondly, the force with which the blood is propelled into it, and against certain parts of it. These predisposing causes are well illustrated by the frequency of aneurisms in the arch of the aorta, into which the blood is thrown with considerable force, and with a remarkable impetus

against certain parts of its parietes. Thirdly, I may specify, as another predisposing cause, such a situation of an artery as exposes it to be greatly disturbed by the motions of the part or limb, while it does not receive adequate support from any surrounding muscles. It is to these circumstances that many surgeons ascribe the frequency of aneurisms in the ham, where the position in which the limb is often placed occasions an angle in the artery, and that at a point where the vessel receives no support from the immediate contact of any muscles. Perhaps, gentlemen, this explanation ought to be looked at with suspicion; and, although I am rather sceptical about its validity myself, it may deserve your consideration; for we certainly find that popliteal aneurism is particularly frequent in persons who are in the habit of sitting long with their knees bent, and at the same time subjected to continual concussion. Thus, the disease is very common in coachmen, post-chaise drivers, and postilions, who sit for a long time with the knee bent, and the popliteal artery exposed to protracted and violent concussions.

The atheromatous and calcareous deposits which take place between the internal and middle coats of arteries, and which are often the forerunners of aneurism, sometimes pervade an extensive, and even the greater, portion of the arterial system, and, consequently, there may be several aneurismal tumours at one time in the same person. In an example, recorded by Pelletan, they amounted to the extraordinary number of sixty in the same individual, varying in size from the magnitude of an egg to that of a common nut. The particulars of this case you may read in his *Clinique Chirurgicale*. If an artery be sound, you will find, on stripping off its outer coat, that the want of the support afforded by that texture will not give rise to aneurism; neither will the application of a tight ligature which cuts through the internal and middle coats produce that effect. I mean to state, that if you were to apply a ligature very firmly to an artery, and immediately afterwards to take it off the vessel, the division of the middle and inner coats by it would not lead to the formation of aneurism, provided the artery were previously healthy. Mr. Warner does

VOL. IV.

S

indeed relate one extraordinary case, in which an aneurism followed the application of a ligature to the brachial artery; but here we must suppose that some unusual state of the vessel—some unsound condition of it, must have existed previously to the application of the ligature.

Then another fact, relative to aneurism of the brachial artery and its branches is, that you rarely notice a diseased state of them antecedently to the commencement of aneurism in them; you do not find that aneurisms of these particular arteries are preceded by atheromatous or calcareous depositions between the coats of the vessels; but they generally arise from wounds. On the contrary, aneurisms of the axillary, popliteal, and the generality of other arteries, are preceded by a morbid change in the coats of these vessels. Men are found to be more frequently the subjects of aneurism than women; and Mr. Hodgson of Birmingham, who kept a list of a considerable number of aneurisms, with the particulars of which he was acquainted, sets down fifty-six as having occurred in male subjects, and not more than about half a dozen in females. You may, therefore, conclude, that aneurisms are about nine times more frequent in men than women. Then, with respect to the period of life at which the disease is most common, I may observe, that it is between the ages of thirty and fifty years, a time of life when the muscular system still retains a considerable degree of strength, and the arterial system begins to incline to those changes, which predispose it to this disease. In fact, we know that, if the arteries are not in a sound state, great muscular exertion may really become the exciting cause of aneurism, so that the frequency of this disease between the ages I have mentioned is readily accounted for. However, aneurisms are occasionally met with in some persons under thirty, and in others above fifty. Sir Astley Cooper mentions one instance which occurred in a subject eighty years of age, and another which took place in a boy only eleven years of age.

Popliteal aneurism is rare in females; and when they are the subjects of aneurism, the disease is generally situated either in the aorta, especially its arch, or in the carotid artery. Of course they are just as liable to aneurism from the wound of a large artery, in any situation, as men are; and, indeed, they are sometimes seen with aneurism of the brachial artery, occasioned by the lancet in the unskilful performance of venesection.

The prognosis in aneurism deserves, gentlemen, your serious consideration. An aneurism that is left to take its own course will generally have a fatal termination; if an external aneurism, the patient will ultimately be destroyed, either by the bursting of the tumour and the consequent loss of blood, or by gangrene of the limb; or, if the case be an internal aneurism, he will be destroyed either by the pressure of the tumour on important organs, or by the rupture of the aneurism,

and the effusion of blood into a variety of situations and directions. I believe these are the general modes in which the disease proves fatal. I might mention, however, another one, where the patient dies from the effects of inflammation and gangrene of the tumour itself upon the constitution, which is sometimes not able to bear the sympathetic disturbance excited by this state of the local disease. However, the fatal terminations of aneurism are most commonly induced first by hæmorrhage, secondly by gangrene of the limb, as is exemplified when the aneurism changes from the circumscribed into the diffused form, in which event, the cellular membrane becoming sometimes enormously injected with blood, the circulation is obstructed, and the limb mortifies; and, lastly, the pressure of the tumour on an important organ may destroy life, though the aneurism may not burst at all, as was illustrated in the case from which Cruveilhier's plate that was on the table yesterday was taken. In that example, you know, the aneurismal swelling obliterated a portion of the pneumo-gastric nerve, and made such pressure on the trachea, that the patient's dissolution was the result. For the most part, internal aneurisms either make their way gradually through the parietes of the chest or abdomen, and produce a fatal hæmorrhage by bursting externally, or they burst into some viscus, cavity, or passage with the sides of which they happen to be in contact, and to which they have previously contracted adhesions. Thus we find they often burst into the pericardium, the œsophagus, the trachea, and sometimes into the intestinal canal, and other parts. Aneurisms of the limbs generally prove fatal by bursting externally; but they may also give way under the integuments, and then the blood, by becoming extensively diffused in the cellular membrane, may obstruct the circulation, and give rise to mortification. All these terminations of aneurisms deserve, gentlemen, to be recollected, for the knowledge of them you will find valuable in practice.

On account of the impossibility of performing a surgical operation for the cure of many internal aneurisms, and also because such diseases affect vessels into which the blood is propelled with extraordinary force, the prognosis in internal aneurisms is more unfavourable than in external ones. The former likewise may produce serious danger by their pressure on important organs; a consideration, which does not prevail so much with respect to external aneurisms; indeed I have already explained to you, that internal aneurisms will sometimes destroy the patient, without bursting at all, merely by interrupting or disturbing the function of some organ essential to life. The prognosis must also be unfavourable, if the patient has more than one aneurism at the same time, for this circumstance indicates a morbid state, or tendency to disease, throughout the arterial system, and if the operation were performed for the cure of one aneurism,

the patient might soon afterwards die of another. It is necessary, therefore, when you are considering the propriety of an operation for an external aneurism, to take into your calculations, whether there be any symptoms denoting the probability of the existence of an internal aneurism at the same time. The fact to which I now invite your attention, must convince you at once of the justness of this advice. The patient, from whom this heart was taken, had an operation performed on him for a popliteal aneurism, and, three months afterwards, he died of the rupture of an aneurism at the root of the aorta, the blood from which filled the pericardium. The operation, therefore, was worse than superfluous, as subjecting the patient to pain, without the prospect of any benefit in return for his suffering. I will hand the preparation to you, and you will see a bristle in the crevice, through which the blood of the aneurism passed into the pericardium. Nothing can justify operating on a patient who has an internal aneurism, as well as an external one, except the circumstance of saving him from immediate death from hæmorrhage already begun or about to begin. In any other state of such a patient, I think, it would not be proper to perform the operation. As Sir Astley Cooper was once performing the operation for an external aneurism, directly he had made the first incision in the course of the femoral artery, the patient fell backwards and died instantaneously. Now, on opening him, the same occurrence was seen, as is illustrated by that preparation, which you are examining; the pericardium was found full of blood in consequence of a rupture of an aneurism situated at the root of the aorta, and, gentlemen, here I may repeat, what I explained to you in the last lecture, namely, that aneurisms at the root of the aorta usually burst while they are very small; for this portion of the aorta is not covered by any elastic sheath, instead of which it has a covering reflected over it from the pericardium, a production that will not bear much distension, but cracks suddenly, and then the pericardium is filled with blood. But if there were two aneurisms on the same limb, (for sometimes there will be an aneurism in the ham and another in the thigh at the same time) what would then be the right practice? The simultaneous existence of two aneurisms certainly indicates a disposition to the disease in the arterial system at large, yet, in the case under consideration, the operation ought to be performed, because it may be the means of curing both aneurisms. In fact, the plan has been adopted with success; and the case is materially different from an external aneurism complicated with an internal one. I have next to inform you, that the size, as well as the situation of an aneurism makes an important difference in the prognosis; generally speaking, the larger the aneurism is, the more tedious and uncertain is the treatment of it; for the magnitude of the tumour may materially interfere with the re-establishment of

the collateral circulation. When the swelling has been allowed to become very large, before the operation is performed, its pressure will frequently obliterate the most important anastomosing vessels, and sometimes also totally change the form and texture of large nerves in the vicinity of the aneurism. For example, an aneurism in the ham sometimes changes the popliteal nerve into a flat riband-shaped expansion, so as to be with difficulty recognised; indeed, in the case to which I alluded yesterday, where I was obliged to amputate, I asked a friend, who dissected the limb after its removal, what was the state of the popliteal nerve? when he said that he had some difficulty in making it out, so greatly had it been altered in its shape and texture by the pressure of the aneurismal tumour. But, gentlemen, I may also remark, that, when an aneurism has become very large, before the operation is performed, other disadvantageous effects are produced, for instance, the principal veins may be obliterated, and if it be a popliteal aneurism, the bones of the knee and the joint itself may suffer, and, in this case, if the patient were to recover from the aneurism, he might remain a long time, and perhaps permanently, a cripple. Generally, however, this does not happen, for, as I explained on a former evening, the impaired state of the bones does not in general give much trouble after the aneurism has been cured; still every precaution should be taken, by operating in good time, to prevent the possibility of the patient's remaining lame for life, and perhaps losing his leg; for a few instances have occurred, in which amputation was rendered necessary, after the aneurism had been cured, by the state of the knee-joint. Another reason against allowing an aneurism to continue increasing for a long time, is, that the sac may suddenly give way, and the aneurism change from the circumscribed into the diffused form, which is a change greatly for the worse, inducing a serious risk of mortification, and that whether the artery be tied or not, after the effusion of blood into the cellular membrane has once taken place.

When the aneurism is a single one, and so situated as readily to admit of the vessel leading to it being secured, and the patient is otherwise healthy, the prognosis is favourable, provided the operation be done according to the best principles, for much of the patient's safety will depend after all on the manner of operating, and on due attention being paid in its execution to certain maxims, which are acknowledged and valued by all the best practical surgeons of this country, and of every other country in which surgery is combined with science.

I next come to the consideration of the *spontaneous cure of aneurisms*. An aneurism that is not subjected to any kind of surgical treatment, does not always terminate fatally; and, in a very limited number of instances, a cure is effected by natural processes. Now, there are various ways in which a cure

may be brought about spontaneously. The most common manner is by the sac becoming filled with lamellated blood, a change which is indicated in external aneurisms by the tumour losing its pulsation, and assuming a more solid and incompressible consistence. When this has taken place, the blood cannot continue to pass into the sac, but is obliged to take another channel; the lamellated blood is then absorbed by degrees, and a portion of the artery, above and below the aneurism, is finally obliterated or converted into a ligamentous shred or filament. This is what happens in external aneurisms. But, in the aorta, when the cure takes place spontaneously in this way, the vessel may still retain its pervious state, as you see was the case in the example from which this engraving of Mr. Hodgson's was taken. It is an aneurism of the arch of the aorta, in which an aperture still remains, three quarters of an inch in diameter; you see that the sac is in a great measure filled up with lamellated blood; it is nearly filled already, and would probably have been completely so, if it had not been for a circumstance which I shall mention to you directly. In the lower part of the lamellated blood there is a cavity, from which the arteria innominata proceeds, and this cavity, which remains unfilled up by lamellated blood, seems left, as if it were for the purpose of transmitting the circulating fluid blood into the arteria innominata. If it had not been for this circumstance, there can be no doubt, that the sac would have been completely filled up with the lamellated coagula. But, gentlemen, incomplete as the curative process was, all chance of the aneurism bursting was removed, and the aorta, so far from being diminished in size, is actually larger than in the natural state. This case also shows how an aneurism of the arch of the aorta may make the trachea curve forwards. Here is a view of another aneurism, situated about that part of the aorta, from which the cœliac axis originates, and you will see in the engraving, which is taken from one of Mr. Hodgson's specimens, that the canal of the aorta is preserved, though the sac of the aneurism is completely filled up. In another plate before us, you see an illustration of the fact, that an aneurism may include the whole circumference of an artery, though such a case is rare; here the deposition of lamellated blood in the sac of an aneurism of the femoral artery has taken place in such a way as to leave a channel for the passage of the blood through its centre, larger than the original canal of the artery itself; the sac extends from the origin of the epigastric artery to that of the profunda. This specimen certainly appears to be at variance with the opinion, that an aneurism cannot include the whole circumference of the artery; at all events, the dilatation seemed to Mr. Hodgson to occupy the whole circumference of the vessel, and the lamellated blood was deposited upon the interior of such dilatation,

so as to leave a channel through the centre of the solid mass.

Another mode in which the spontaneous cure of an aneurism may be brought about, is by the pressure of a portion of the aneurismal tumour itself on the artery leading to it; sometimes the tumour will overlap the artery above it, and thus cut off the flow of blood into it. Here the cure is effected on the same principles as are dictated by the most approved surgery.

A third manner in which a spontaneous cure may take place, is when the whole aneurismal tumour happens to inflame, suppurate, or even to mortify: here, if the patient can support all the constitutional disturbance produced by the process, and if the inflammation extend deep enough to block up with coagulable lymph the communication between the artery and the aneurismal sac (for this is essential), a cure will be the result. I have seen a considerable aneurism of the femoral artery cured in this manner, that is to say, by a sloughing of the whole tumour; but if the inflammation should happen not to extend to a sufficient depth, the patient, on the separation of the sloughs, may bleed to death.

Fourthly, a spontaneous cure may be accomplished by the pressure of one aneurism obliterating the artery leading to another aneurism. Mr. Liston, of Edinburgh, had a patient with an aneurism of the subclavian artery, which after a time subsided and got well; he afterwards died suddenly, and on examination, it was found that a cure had been accomplished by the pressure of an aneurism of arteria innominata on the subclavian artery, or that leading to the axillary aneurism; the bursting of the former of which had led to the patient's death. The cure took place on the same principle as that where an aneurism cures itself by pressing upon the artery.

In whatever manner the cure is effected, the artery will be found to be converted into a dense impervious cord, those instances excepted to which I have alluded. What would have been the termination in this case (*pointing to the engraving representing the sac of an aneurism of the aorta filled with lamellated blood, through which was left a passage for the blood to flow into the arteria innominata*), it is difficult to say.

Gentlemen, I now come to the consideration of the general principles to be attended to in the treatment of aneurisms. As the enlargement of an aneurism and its ultimate rupture clearly depend on the impetus with which the blood is thrown into the sac, it must be evident to you, that one great principle in the treatment will be to diminish the force of the current of blood into the sac, and even to prevent its continuance altogether. These may be said to be the leading principles in the treatment of aneurisms, either to diminish the force of the current of blood into the aneurism, or to cut it off altogether. The

latter is the only method on which full dependence can be placed, I mean the method of preventing entirely the continuance of the flow of blood into the aneurismal sac. Unfortunately, however, we cannot always put this principle in execution; we cannot always do those things which are necessary to carry it into effect; for instance, we cannot apply the principle to many internal aneurisms. Under these circumstances, we are obliged to be content with such measures as are calculated to reduce the force of the circulation generally, by which means we lessen the velocity of the flow of blood into the sac of the aneurism, as well as into other parts. In an aneurism of the aorta, a very low diet, abstinence from animal food, occasional venesection, the exhibition of digitalis, and the avoidance of rough exercise, constitute the common plan of treatment. I need hardly say, it is necessary to avoid all laborious pursuits, and every thing which tends to accelerate the circulation. The treatment on these principles, which was first suggested by Valsalva, does not often succeed in curing the disease; some instances are indeed mentioned by Pelletan, in which he succeeded in curing aneurism by the employment of these measures, but it is what cannot in general be expected. I have seen an aneurism of the aorta considerably reduced by the first hæmorrhage which took place from it; the sac in this instance burst into the œsophagus; the patient fainted after losing a considerable quantity of blood, some of which escaped by the mouth, and the rest passed into the stomach, the bleeding then stopped, and the patient lived three months after this without any copious return of hæmorrhage. In the meantime, the swelling, which had displaced the scapula in a remarkable degree, completely subsided, seemingly in consequence of the great quantity of blood that had been lost. However, at the end of three months, another hæmorrhage carried the patient off, and, on examination of the body, an ulcerated communication, between the œsophagus and the aneurismal sac, was detected. This case seems completely to prove, that an aneurism, even of the aorta itself, may be considerably diminished by depletion. However, now that I am speaking of copious hæmorrhages, I must give you one caution, which is this, never to take away much blood at a time from a patient afflicted with aortic aneurism; for, if he should happen to faint, there would be a considerable risk of his not reviving. On this account, when you bleed for internal aneurisms, you must take away only a few ounces at a time from a small orifice, and the patient should be bled in the recumbent position. Surgeons of the greatest experience have found, that there is serious risk incurred by exposing the patient to the chance of fainting, by bleeding him too boldly for an aneurism of the aorta.

Sometimes surgeons endeavour to cure external aneurisms, also, on the principle of lessening the impetus of blood into the aneurismal sac; but this treatment has not been

attended with much success. With this object in view, a bandage has been applied with the nicest possible equality on the whole limb, and thus the current of blood through the member has been lessened, and a beneficial effect produced on the disease. Here a different principle is acted on, than when pressure is made with a bandage or tourniquet applied to the artery, immediately above the tumour; the latter plan does not diminish the circulation in the whole limb, but it cuts off the force of the circulation in the portion of the artery leading directly into the sac, but there is great difficulty in fulfilling the latter principle, and, on account of the pain produced, the patient will generally be unable to bear the pressure long enough. The other plan of equable pressure on the whole limb was preferred by Scarpa, but he had not much success with it. When you choose to try pressure, you apply cold to the limb at the same time, and put the patient on such a plan of living as shall lessen the circulation generally; he must be enjoined spare diet; his limb must be kept perfectly quiet, and the pressure applied equally all over it, so as to prevent pain and the risk of gangrene.

We know by experience, that, with respect to external aneurisms, there is only one plan of treatment that can be depended on, and that consists in cutting off the current of blood into the sac, by tying the artery at some convenient point above the tumour, or on that side of it which is nearest the heart. By doing this, we not only cut off the current of blood into the sac for the present, but by applying a ligature on the artery, we do what will lead to such changes in the tied portion of the vessel, as will permanently prevent the blood from entering the sac. When the ligature is applied, the pulsation sometimes immediately ceases altogether, and, in every instance, it is materially reduced, for you must remember, that the ligature does not absolutely and constantly prevent all the blood from entering the tumour, because, after the main artery has been tied, a quantity of that fluid may still pass into the sac through the collateral branches, and this sometimes in sufficient quantity to keep up the pulsation. Nay, such pulsation may even continue for a short time to increase, so as to alarm the practitioner. But this circumstance should not give him much uneasiness, for the operation will seldom fail on this account. The main artery having been tied or obliterated, the current of blood is always considerably retarded, though a small quantity of it may still flow through the sac; hence the lamellated coagula form more quickly, and, after a time, the degree of pulsation which may have continued, or returned, will gradually subside, and the aneurism will ultimately be absorbed. If the throbbing should not abate, or were it to become very strong, it might be right to bleed, employ cold applications, and prescribe digitalis.

To-morrow, gentlemen, I hope to finish all that I have to say on the subject of aneurisms, except what relates to operations for them.

A LIST OF THE MEDICAL AND SURGICAL SCHOOLS IN LONDON.

SESSION 1833-34.

UNIVERSITY OF LONDON.

FACULTY OF MEDICINE.

THE Lectures commence on the 1st of October, and continue to the beginning of May. For the convenience of students, some of the courses may be divided into two parts, and a separate payment be made for each.

The payments stated below for each class are made by students nominated by proprietors: those not nominated pay 5s. additional for every pound until this extra payment amounts to 4l. 10s.

An University fee of 10s. for one class, and 1l. for two or more classes, is paid by each student every session; where, however, the course is of short duration, this fee is diminished. The *Matriculation Fee* of 2l. relieves the student, during the whole course of his study, from the university fee.

All fees are paid at the office of the university, where the student receives his tickets, which he afterwards takes to be countersigned by the Professor. The office is open from nine till five, except on Saturday, when it closes at two.

The payment of the fee for the first division, and double the fee for the second division, gives in most classes perpetual admission, provided the student is matriculated.

Weekly examinations are held in every class; and those pupils only who have regularly attended these examinations will be admitted to contend for honours at the close of the session.

LECTURES.

Anatomy and Physiology; Professor, Dr. Quain. Every day, except Saturday, from two to three. Payment to the University for the entire course, 7l.; or for the first division, 4l., for the second, 3l. Perpetual, 10l.

The object of these lectures is, to lead the student, by a methodical system of instruction, to a correct knowledge of human anatomy and physiology, and to make him familiar with the applications which should be made of the facts and principles set forth, as well as their subservience to the practical business of medicine and surgery.

The course is divided into three sections. In the first will be considered the solid and fluid constituents of the body—their characters and properties; the division of the solids into their primary tissues,—the classification of these—their conformation and structure, physical and vital properties. This part of the course embraces the subjects usually included under the head "*General Anatomy*," and serves as an introduction to the others, as it affords an opportunity for the explanation of the principles on which the nomenclature of anatomy has been constructed, and of exhibiting some general views of the animal economy.

Descriptive and Structural Anatomy forms the subject of the second section. The osseous system with its connecting media (ligaments and cartilages) will be fully described, and then successively, each in its proper order, the muscular system, the vessels and nerves, and the various organs contained within the skull, thorax, and abdomen. The description will comprise all that relates not only to the form, position, and relations of organs, but to their intimate composition and structure.

This section will conclude with a series of demonstrations of the more important regions of the body, viewed in their practical relations to operative surgery.

The third section will be devoted to *Physiology*, and will exhibit general views of the functions and uses of the different parts and organs previously described, considering them in their various adaptations to the support and well-being of the individual, the maintenance of his relations with the external world, and the continuance of the species.

Morbid Anatomy; Professor, Dr. Carswell; Tuesdays and Fridays, from ten to eleven. Fee 3l.

The object of this course is to make the student acquainted with the modifications of organisation which constitute a state of disease, or a deviation either of the normal composition or conformation of organs. Considered individually, the physical, anatomical, chemical, and physiological characters of each will be described first; and afterwards the phenomena by which they are characterised, and the modifications which they undergo in the different tissues, systems, and organs of the body, will be pointed out and explained. And as this branch of medicine is intimately connected with the practical study of diseases, the modifications of organisation of which it treats will also be considered in relation to the causes by which they are produced, the effects to which they give rise, and the remedial means which may be employed for their cure or prevention.

Independently of the facilities which the specimens of organic diseases, preserved in the Museum of the University, afford, for the illustration of these lectures, great additional advantage will be derived by the student, from the use which will be made of a large collection of coloured delineations, representing many of the more important organic phenomena, which these diseases present during life or after death. Every effort will likewise be made to obtain recent specimens of disease, that the practical knowledge necessary to be acquired by the student on this subject may be made as complete and useful as possible.

Practical Anatomy; Richard Quain, Esq. Eleven to twelve. Payment to the University for the whole course, 5l.; first division, 3l., second division, 2l. Perpetual, 8l.

The demonstrations are intended to form complete courses of instruction in practical anatomy. With this view the body will be considered as divisible into a series of sections

or regions, each of which will be made the subject of separate examination, and its several constituents (bones, muscles, vessels, &c.) fully described before the consideration of any other part is entered on. By pursuing this plan, descriptive anatomy is presented to the pupil in a manner different from that adopted in the Professor's lectures, at the same time that the demonstrations are made subservient to the business of the dissecting room, namely, the study of *Practical Anatomy*.

Surgical Anatomy will form a separate section of the spring course. The different regions of the body which most frequently become the seat of accidents or diseases, requiring surgical operations, will be described; the various operations will be performed, and the relative merits of different methods of operation discussed. The students will have an opportunity of repeating the operations under Mr. Quain's direction.

In the dissecting-rooms the pupils will be assisted and directed in their studies during several hours daily.

Principles and Practice of Medicine; Professor, Dr. Elliotson, every morning, except Saturday, eight to nine. Payment to the University for the entire course, 5*l*.; first division, 3*l*.; second division, 2*l*.; perpetual 7*l*.

These lectures are illustrated by preparations from the museum of anatomy and a large collection of coloured drawings, exhibiting the various structural changes which disease occasions; and whenever it is practicable, recent morbid specimens will be presented to the class.

Principles and Practice of Surgery; Professor, Samuel Cooper, Esq., Monday, Tuesday, Wednesday, and Thursday, seven to eight. Payment to the University for the entire course, 4*l*. 10*s*.; perpetual, 6*l*.

First Division. Injuries and diseases common to the whole or several parts of the body.

Second Division. Injuries and diseases of individual organs and regions.

Third Division. The operations of surgery explained, and demonstrated on the dead subject.

Midwifery and Diseases of Women and Children; Professor, Dr. D. Davis, every morning, nine to ten. Payment to the University for the entire course, 5*l*.; first division, 3*l*.; second division, 2*l*.; perpetual, 7*l*.

The subjects of this course will be included under three principal departments, viz. anatomical, physiological, and pathological or practical: the two former treat of the structures and functions of the parts and organs concerned in the practice of midwifery; the latter, of the actual practice of the art itself.

Under this principal division of the course will be given instructions for the obstetric and medical treatment of all varieties of labours, natural, preternatural, complex, and instrumental, together with ample histories of the most important diseases incident to the human female during the several epochs of her life,

but most especially during pregnancy, and in the puerperal state.

The last section of the course will treat of the principal ailments of infants during the month; of eruptive and other diseases of the skin; of diseases of the alimentary organs; of the morbid phenomena incident to the process of dentition; of convulsions, and of hydrocephalus.

Materia Medica and Therapeutics; Professor, Dr. A. T. Thomson, daily, except Saturday, three to four. Payment to the University for the entire course, 6*l*.; first division, 3*l*.; second division, 3*l*.; perpetual, 9*l*.

This course is intended to render the medical student familiar not only with the materials which he is to employ in combating disease; but to teach him also what parts of these materials are active, what inert; and how they operate on the animal economy in the treatment of diseases. For this purpose the various substances employed as medicines are exhibited and described first in their natural state, and afterwards in the form of the different preparations into which they enter. The active principles of each are separated and described; and in many instances the operations necessary for this purpose are performed before the students.

One object of this course is to demonstrate to the pupils the circumstances which modify the effects of medicinal agents on the diseased body. Every part of the course is intended to have a strict reference to practical utility.

For the illustration of his lectures, the Professor of this department has formed a museum, to which the students of his class have access under certain regulations.

Instructions in pharmaceutical chemistry will be given to private pupils in the Professor's laboratory.

Chemistry; Professor, Dr. Turner, daily, except Saturday, ten to eleven. Payment to the University for the entire course, 7*l*.; first division, 4*l*.; second division, 3*l*.; perpetual, 10*l*.

The first two weeks will be employed in taking a general view of the whole science. The following subjects will then be discussed:

1. Heat;—its properties, and its employment in the arts in domestic economy, and in chemistry.

2. Light, chiefly in its chemical relations.

3. Electricity and galvanism.

4. Chemical affinity, doctrine of definite proportions, and the atomic theory.

During the months of January, February, and March, the Professor will give a history of the elementary substances and their more immediate compounds, in the following order:

1. History and properties of the twelve non-metallic bodies, such as oxygen, hydrogen, &c.; and of their binary compounds, such as sulphuric and nitric acids, ammonia, carburetted hydrogen, &c.

2. History and properties of the metals, and their compounds—

F a. With the non-metallic bodies; such as oxides, chlorides, &c.

b. With each other; such as brass, pinchbeck, and other alloys.

3. History of the salts, or the compounds formed by the union of acids and alkaline substances.

4. The nature, properties, and analysis of mineral waters.

The description of organic substances will then be entered on, divided into the two departments of animal and vegetable chemistry.

The subjects discussed in the lectures will be illustrated by experiments, diagrams, and preparations; and a proper course of reading on chemistry will be indicated.

It is an essential part of this course to point out the useful application of the facts and doctrines of chemistry. Accordingly, the processes of the chemical arts, such as bleaching, dyeing, brewing, distilling, &c. will be described and illustrated. The operations of metallurgy and assaying, by which metals are extracted from their ores, and the value of such ores determined, will likewise be considered. The connexion of chemistry with medicine will be traced:—by teaching how to detect the presence of poisonous substances, and to destroy their energy;—by discussing those departments of physiology and pathology which admit of being elucidated by chemistry;—and by explaining the nature of those pharmaceutical preparations which may be regarded as pure chemical compounds, or are produced by complex chemical processes. The chemical phenomena of the material world will also be described;—as, for example, meteorological appearances,—the formation and composition of minerals,—and the changes produced on the surface of the earth by chemical agency.

The Professor will receive a few private pupils, who may work daily in the laboratory in the study of experimental and analytical chemistry. He will give information on the subject to those who apply to him.

Comparative Anatomy; Professor, Dr. Grant, daily, except Saturday, three to four. Payment to the University 3*l.*, commencing the 1st of October, and continuing to the 1st of January.

In this course the organisation of the whole animal kingdom is considered. The varieties presented by the internal organs, and the modifications of their functions, are examined in every class of animals. The lectures and demonstrations are illustrated by recent dissections, by an extensive series of zootomical preparations, and by drawings, &c. The osseous and muscular systems are first examined, from the highest to the lowest classes, and the nervous system and organs of the senses are treated of in the same descending order. The various organs connected with digestion, circulation, and respiration, the structure of the secreting and excreting organs, the structure and development of the gene-

rative organs, and the various modes of reproduction, are examined in all the classes of the animal kingdom.

The physiological details connected with the structure and development of the different systems of organs, and the applications of the facts of comparative anatomy to the structure and physiology of man, and to zoology, geology, and other sciences, are pointed out while demonstrating the various forms of internal organisation presented by the inferior animals.

A second course of comparative anatomy will commence on the 1st of January, and will continue to the 1st of April.

Medical Jurisprudence; Professor, Dr. A. T. Thomson, Wednesday and Friday, four to five.

This subject is now prescribed as a branch of medical education by the regulations of the Society of Apothecaries.

The medical and toxicological departments of the course will be fully treated; and the application of tests, and the various manipulations for the discovery of poisons rendered familiar to the student, whilst the physiological effects of poisons on the animal system, and treatment of the symptoms induced by them, with the appearances which they leave on the body, when they prove fatal, will be indicated.

The object of the legal part of the course will be to point out the description of medical information required in different judicial investigations, and to show, by examples from actual trials, the proper conduct to be adopted by medical men under various circumstances, with a view to the admissibility and value of the testimony that may be expected from them. It will be endeavoured to give the student as practical a notion as possible of the situations in which he may be placed, whether in respect of the receiving or the preparing of medical evidence, or afterwards of communicating it in the presence of a court of justice.

Botany; Professor, Dr. Lindley, Tuesday, Thursday, Friday, and Saturday, eight to nine A. M.

The course for the medical school will commence early in October, and will continue for about six weeks five times a week, one lecture in each week being in the form of an examination; after which there will be a suspension of the lectures till the 1st of April, when they will be resumed for six weeks more.

The autumn course will consist of botanical demonstrations, and an explanation of the manner of judging of the properties and internal organisation of plants by their external characters. The spring course will be occupied in considering the physiology and comparative anatomy of vegetation, and will comprehend the application of these branches of science to agriculture, horticulture, and systematic arrangement.

Payment to the University, 3*l.* Perpetual, 6*l.*

The course is subdivided in this manner in order to enable the students in the medical school to complete their course of botany along with the medical classes, and to meet the regulations of the Society of Apothecaries, and those under which the University diploma is granted. But it would be highly to the advantage of students if they were to extend their attendance to the summer course, terminating in the end of June. Although it answers nominally to that of the autumn, yet the subjects employed in illustration will be so different, that the student will not only have a second opportunity of gaining a practical knowledge of botany, but may do so upon new ground.

Payment to the University for the autumn and spring courses, 4*l*.

The lectures are abundantly supplied with specimens, and are illustrated by drawings, and the occasional use of the microscope.

HOSPITAL AND DISPENSARY.

A hospital has been founded immediately opposite the University, and its erection is rapidly advancing.

The Dispensary in George-street, Euston-square, is attended by four of the medical officers of the University. Fee for twelve months' attendance, 6*l*. 6*s*. House Surgeon and Apothecary, J. Hogg, M.D.

As soon as the hospital shall be opened for the reception of patients, the dispensary will merge in the hospital.

The Museum of Anatomy and a Medical and General Library are open to the medical students, every day from nine in the morning till nine in the evening.

The Council give a certificate of proficiency, which in the medical faculty is called "The Diploma of Master of Medicine and Surgery in the University of London," under conditions which may be learnt at the office.

Veterinary Medicine and Surgery; Lecturer, William Youatt, Esq. These lectures commence on the 1st of November, and will be continued until the 1st of July, with a division at the end of February. Monday and Friday, from six to seven; Tuesday and Thursday, from half-past four to half-past five. Fee for the whole course, 5*l*.; or, for the first division, 3*l*.; second division, 2*l*. Perpetual, 7*l*.

In these lectures the structure of the horse, the ox, the sheep, and the dog, will be described, with especial relation to their usefulness:—the diseases to which they are liable, the nature and causes of those diseases, and the medical and general treatment of all domesticated animals, will be taught. To the medical student these lectures will show the difference of disease as depending on difference in the structure of animals, and the great difference in the treatment of the same disease, and the effects of the same medicine. To the agriculturist they will unfold the principles on which the usefulness

and health of the horse and cattle depend, and they will prepare the veterinary pupil for the practice of his profession. The whole will be illustrated by a veterinary museum.

(By order of the Council.)

THOMAS COATES, *Secretary*.

May, 1833.

KING'S COLLEGE,

MEDICAL STUDENTS.

In establishing a School of Medicine and Surgery in King's College, the Council have been influenced by the belief, that many individuals who intend their sons for the medical profession, will gladly embrace an opportunity of placing them in connexion with an institution, which has for its principal object to educate the rising generation in the doctrines of Christianity, as taught by the established church, and to fix in their minds the true principles of morality. They believe, likewise, that every one who has the welfare of society at heart, and who has considered the most effectual means of promoting it, will feel an especial interest in the success of this part of their undertaking; under the conviction, that the duties which devolve upon the medical profession are such as to render the religious and moral character of its members not less important than their practical and scientific attainments.

The Council are indeed aware that the great majority of medical students, during the time of their residence in the metropolis, have so many demands on their attention within the limits of their own peculiar pursuits, as to leave them but little leisure for other branches of study. They expect, however, that all who belong to the class of King's College students of medicine and surgery, will be regular in their attendance at divine worship in the College chapel on Sundays in the forenoon; and they hope that the students may be able to avail themselves, to a certain extent at least, of the opportunities of religious instruction offered by the lectures of the principal.

The Council earnestly recommend, that those who have it in their power, should devote themselves for some time to the general studies of the College before they enter upon that course of instruction, which is more exclusively professional.

The medical classes in King's College open on the first of October, and close early in May.

The session is divided into two terms, of which the second begins on the twenty-first of January.

Those who are desirous of attending the medical and surgical lectures at King's College, have the option of entering, either as King's College medical students, to go through a fixed course of professional study, or as occasional pupils, to attend the lectures of particular professors.

The course of study which King's College medical students are expected to follow, comprises all those subjects, a knowledge of which, attested by certificates of attendance upon lectures, is required by the College of Surgeons and by the Society of Apothecaries, as a condition of obtaining their respective diplomas.

King's College students have the privilege of competing for all the prizes, which are offered annually for superior proficiency in the subjects of the lectures. The gold medals given for general medical proficiency are exclusively awarded to King's College regular students. Those among the occasional students, who enter as perpetual pupils to the lectures of any single professor, are at liberty to compete for the prizes offered in their class.

The regular students of the College have access to the general, as well as the medical library, and are allowed the use of the books. They are alone permitted to wear the College gown.

Special certificates, in addition to those which relate to medical proficiency, are given for general correctness and propriety of conduct in the College, and for regularity of attendance at divine service; also to those students who shall have attended the lectures on religious and moral subjects, and shall be found to have profited by them.

Terms of attendance upon the Medical and Surgical Lectures separately, when the Student shall not enter for the whole course of medical study.

Anatomy, Physiology, and Pathological Anatomy, by Herbert Mayo, Esq. F.R.S., Surgeon to the Middlesex Hospital. First course, 5*l.* 5*s.*; second course, 4*l.* 4*s.*; third course, 3*l.* 3*s.*; unlimited attendance, 10*l.* 10*s.*

Anatomical Demonstrations, by Richard Partridge, Esq. First course, 3*l.* 3*s.*; second course, 3*l.* 3*s.*; third course, 2*l.* 2*s.*; fourth course, 2*l.* 2*s.*; unlimited attendance, 8*l.* 8*s.*

Botany, by Gilbert Burnett, Esq. F.L.S. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; unlimited attendance, 4*l.* 4*s.*

Chemistry, by J. F. Daniell, Esq. F.R.S. First course, 4*l.* 4*s.*; second course, 3*l.* 3*s.*; third course, 3*l.* 3*s.*; unlimited attendance, 8*l.* 8*s.*

Materia Medica and Therapeutics, by Bisset Hawkins, M.D. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; third course, 2*l.* 2*s.*; unlimited attendance, 6*l.* 6*s.*

Medicine, Principles and Practice of, by Francis Hawkins, M.D., Physician to the Middlesex hospital. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; third course, 2*l.* 2*s.*; unlimited attendance, 6*l.* 6*s.*

Forensic Medicine, by Thomas Watson, M.D., Physician to the Middlesex Hospital. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; unlimited attendance, 4*l.* 4*s.*

Midwifery, and Diseases of Women and Children, by Robert Ferguson, M.D. First

course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; third course, 2*l.* 2*s.*; fourth course, 2*l.* 2*s.*; unlimited attendance, 6*l.* 6*s.*

Surgery, Principles and Practice of, by J. H. Green, Esq. F.R.S., Surgeon to St. Thomas's Hospital. First course, 4*l.* 4*s.*; second course, 3*l.* 3*s.*; unlimited attendance, 6*l.* 6*s.*

Two courses of lectures are delivered during the session upon each of the following subjects:—*Anatomy, Materia Medica and Midwifery*; a single course is given upon *Forensic Medicine*; and upon each of the remaining subjects a single extended course, divided into two parts.

The course of study which the King's College medical students are required to attend, in order to enable them to pass the examinations at the College of Surgeons and Apothecaries' Hall, comprises the following lectures, of which the terms are annexed:—

	Courses.	Payment.
Anatomy, Physiology, and		£. s.
Pathological Anatomy	4 .	10 10
Anatomical Demonstrations,		
with Dissections	4 .	8 8
Botany	1 .	3 3
Chemistry	2 .	7 7
Materia Medica	2 .	5 5
Medicine, Practice of	2 .	5 5
Forensic Medicine	1 .	3 3
Midwifery	2 .	5 5
Surgery	2 .	6 6
		£54 12

For students nominated by proprietors this sum is reduced to Fifty Pounds.

The payment for attendance, as King's College medical students, may be made either at once, or half the sum may be paid at the commencement of the first term, and the remainder at the commencement of the second term of their attendance. Medical students are allowed to begin their attendance either in the October or January term. King's College medical students pay a *Matriculation Fee* of 1*l.* 1*s.* on their admission; as well as a fee of 1*l.* 1*s.* for admission to the medical reading-room, and the use of the books, both in that and the general library, so long as they shall attend any of the College courses of lectures.

A Museum and Library are attached to the College, to which, under proper regulations, the students have daily access.

Those who desire it have the opportunity of attending a course of medical Latin, for which the fee is 3*l.* 3*s.* each term, for instruction four hours in each week.

The following are the days and hours when the different Lectures in the Medical Department are delivered.

Botany.—Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday, from 8 to 10 in the forenoon, in the early part of the October term; and in the Spring, every day ex-

cepting Wednesday, when the lecture begins at 3 o'clock.

Principles and Practice of Medicine—Monday, Wednesday, and Friday, from 9 to 10 in the forenoon.

Chemistry—Tuesday, Thursday, and Saturday, from 9 to 10 in the forenoon.

*Anatomical Demonstrations**—Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday, from 10½ to 11 in the forenoon.

Materia Medica and Therapeutics—Monday, Wednesday, and Friday, from 11 to 12 in the forenoon.

Midwifery, and the Diseases of Women and Children—Tuesday, Thursday, and Saturday, from 11 to 12 in the forenoon.

Interval for hospital attendance, or Practical Anatomy, from 12 to 3 o'clock.

Anatomy, Physiology, and Pathological Anatomy—Monday, Tuesday, Thursday, Friday, and Saturday, from half-past 2 to half-past 3 in the afternoon.

Principles and Practice of Surgery—Monday, Wednesday, and Friday, from 8 to 9, P.M.

Forensic Medicine—Tuesday, and Thursday, from 4 to 5, P.M.

ST. BARTHOLOMEW'S HOSPITAL.

The medical officers and lecturers of the hospital announce, that, at the conclusion of the season, a competition will be opened in each department of the school, to those students who may be disposed to engage in it; and that prizes, with other distinctions, will be publicly awarded to such as may show superior talents and proficiency.

LECTURES.

Medicine, by Clement Hue, M.D., Fellow of the Royal College of Physicians, and Physician to St. Bartholomew's and the Foundling Hospitals; on Tuesdays, Thursdays, and Saturdays, at ten o'clock in the morning.—Terms: Single course, four guineas; perpetual, seven guineas.

Clinical Lectures on Medicine, by Clement Hue, M.D.

Clinical Lectures on Medicine, (in the wards of the hospital,) on Mondays and Wednesdays, at eight o'clock in the morning, by P. M. Latham, M.D., Fellow of the Royal College of Physicians, and Physician to the Hospital.

Surgery, by William Lawrence, F.R.S., Surgeon to the Hospital; on Mondays, Wednesdays, and Fridays, at seven o'clock in the evening.—Terms: One course, five guineas; unlimited, eight guineas.

Occasional Clinical Lectures on Surgery, by Henry Earle, F.R.S., Surgeon to the Hospital.

Chemistry, by Clement Hue, M.D.; on Mondays, Wednesdays, and Fridays, at ten o'clock in the morning.—Terms: Single course, four guineas; perpetual, eight guineas.

Materia Medica and Pharmacy, by Clement Hue, M.D., on Tuesdays, Thursdays, and Saturdays, at a quarter-past eleven in the morning.—Terms: Single course, three guineas; perpetual, four guineas.

N. B.—Gentlemen entering as perpetual pupils to both the lectures on medicine and chemistry, are considered as perpetual also to materia medica and clinical lectures.

Natural and Morbid Anatomy and Physiology, by Edward Stanley, F.R.S., Assistant-Surgeon to the Hospital, daily, at half-past two o'clock.—Terms: First course, five guineas; second course, four guineas; third course, three guineas; unlimited, ten guineas.

Practical Anatomy, with Demonstrations, by Mr. Wormald.—Terms: Single course, three guineas; unlimited, ten guineas. The demonstrations daily, at nine in the morning.

Midwifery, and the Diseases of Women and Children, by John T. Conquest, M.D., F.R.S., on Tuesdays, Thursdays, and Saturdays, at seven o'clock in the evening.—Terms: One course, three guineas; two courses, five guineas; perpetual, eight guineas.

Forensic Medicine, by George Leith Roupell, M.D., Fellow of the Royal College of Physicians, and Physician to the Foundling and Seamen's Hospitals, and George Burrows, M.D., Fellow of Caius College, Cambridge, and of the Royal College of Physicians, London, on Mondays, Wednesdays, and Fridays, at eleven o'clock in the morning.—Terms: One course, three guineas; perpetual, four guineas.

Botany, by Frederic John Farre, M.A., L.M., daily, at four o'clock.—Terms: One course, two guineas; perpetual, three guineas. Herbarising excursions during the summer.

The museum of anatomy is open every day.

Reading room, with a library of reference for the use of the students.

Morbid inspections as opportunities occur.

GUY'S HOSPITAL.

Theory and Practice of Medicine; Dr. Bright and Dr. Addison, Mondays, Wednesdays, and Fridays, at half-past three o'clock. First course, 4*l.* 4*s.*; second course, 3*l.* 3*s.*; third and to be perpetual, 2*l.* 2*s.* Two courses paid for at once, 6*l.* 6*s.*; to be perpetual, 3*l.* 3*s.*; three courses, ditto, 7*l.* 7*s.*; to be perpetual, 2*l.* 2*s.* Perpetual, at one payment, 8*l.* 8*s.*

Materia Medica and Therapeutics; Dr. Addison, Tuesdays and Fridays, at seven in the evening, and Wednesday mornings at half-past nine. First course, 3*l.* 3*s.*; second course, and to be perpetual, 2*l.* 2*s.* Perpetual, at one payment, 4*l.* 4*s.*

Morbid Anatomy; Dr. Hodgkin, Curator of the Museum; demonstrations at one o'clock. Lectures perpetual, 2*l.* 2*s.*

* The Demonstrator is present in the dissecting rooms from 11 till 3 o'clock every day.

Clinical Lectures will be given by the physicians.

Midwifery and Diseases of Women and Children; Dr. Blundell, daily, at a quarter before eight in the morning. By single course, each 3*l.* 3*s.*; two courses, paid for at once, 5*l.* 5*s.*; third, fourth, and fifth, each 2*l.* 2*s.* Perpetual, after four single courses, or at one payment, 10*l.* 10*s.*

Physiology or Laws of the Animal Economy; Dr. Blundell, Mondays and Wednesdays, at half-past six in the evening. Single course, 2*l.* 2*s.*; second course, and to be perpetual, 2*l.* 2*s.*; perpetual, at one payment, 3*l.* 3*s.* Pupils of two or more courses of midwifery become perpetual to this by entering for one course.

Botany and Entomology; Mr. C. Johnson, Thursdays at half-past three, Mondays and Fridays at ten. Perpetual, 2*l.* 2*s.*

Principles and Practice of Chemistry; Mr. Arthur Aikin and Mr. A. Taylor, Tuesdays, Thursdays, and Saturdays, at a quarter before ten o'clock. First course, 4*l.* 4*s.*; second course, 3*l.* 3*s.*; third and to be perpetual, 2*l.* 2*s.*; two courses paid for at once, 6*l.* 6*s.*; to be perpetual, 3*l.* 3*s.*; three courses, ditto, 7*l.* 7*s.*; to be perpetual, 2*l.* 2*s.*; perpetual, at one payment, 8*l.* 8*s.*

Medical Jurisprudence; Mr. A. Taylor, Tuesdays and Saturdays, at half-past three. Single course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

Physicians' Pupils; perpetual, 24*l.* 4*s.*; one year, 15*l.* 15*s.*

Anatomy and Operations of Surgery; Mr. Bransby Cooper, daily, at two o'clock. The lectures on the anatomy and diseases of the teeth will be given by Mr. Thomas Bell.

LECTURES.

One course, 5*l.* 5*s.*; two courses, at one payment, 9*l.* 9*s.*; a third course, and to be perpetual, 2*l.* 2*s.*; perpetual, at one payment, 10*l.* 10*s.*

DISSECTIONS.

Single course, each 3*l.* 3*s.*; perpetual, after four single courses, or at one payment, 10*l.* 10*s.*

Demonstrators; Mr. Edward Cock and Mr. Hilton.

Principles, Practice, and Operations of Surgery; Mr. Key and Mr. Morgan, Tuesdays, and Fridays, at eight in the evening. Single course, extending from October to April inclusive) 3*l.* 3*s.*; perpetual, after two single courses, or at one payment, 5*l.* 5*s.*

Comparative Anatomy; Mr. Thomas Bell, Saturdays, at six. Perpetual, 2*l.* 2*s.*

Eye Infirmary; Mr. Morgan, Wednesdays and Saturdays, at twelve.

Sir Astley Cooper, Bart., consulting surgeon.

Clinical Instructions will be given by the surgeons, and on the diseases of women by Dr. Blundell, assisted by Mr. Ashwell.

Surgeon's Dresser; one year, 51*l.* 2*s.*; six months, 32*l.* 12*s.*

Surgeon's Pupils; twelve months, 26*l.* 6*s.*;

six months, 20*l.* a second entry within two months, 6*l.* 11*s.* Pupils entering to the surgical practice of Guy's Hospital are allowed to attend that of St. Thomas's.

Experimental Philosophy; Mr. W. M. Higgins, Wednesdays at five, and Thursdays at six in the evening. Single course, 2*l.* 2*s.*; perpetual, 3*l.* 3*s.*

Pupils will be permitted the use of the library, reading room, and botanic garden, subject to regulations.

N.B. The above lectures are so arranged as not to interfere with each other, nor with the physician's and surgeon's practice.

Mr. Stocker, Apothecary to Guy's Hospital, is authorised to enter to any of these lectures, &c.

Catalogues of the museum may be had by the pupils at the Steward's Office.

No certificate will be given for the Autumnal courses before January, nor for the Spring courses before May.

ST. THOMAS'S HOSPITAL.

LECTURES.

Theory and Practice of Medicine; Dr. Williams; Mondays, Wednesdays, and Fridays, at ten o'clock. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; perpetual, 6*l.* 6*s.*

Principles and Practice of General and Pharmaceutical Chemistry; Mr. R. Phillips, F.R.S.; Tuesdays, Thursdays, and Saturdays, at a quarter before ten o'clock. First course, 4*l.* 4*s.*; second course, 2*l.* 2*s.*; perpetual, 6*l.* 6*s.*

Materia Medica and Therapeutics; Dr. Burton; Mondays, Wednesdays, and Fridays, at four o'clock. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; perpetual, 4*l.* 4*s.*

N.B. The specimens of the materia medica will be open for the inspection of *his pupils*.

Midwifery and the Diseases of Women and Children; Dr. Ashburner and Dr. Rigby; Tuesdays, Thursdays, and Saturdays, at four o'clock. First course, 3*l.* 3*s.*; second course, 2*l.* 2*s.*; perpetual, 5*l.* 5*s.*; labours free of expense.

Medical Jurisprudence; Dr. Lister and Mr. R. Phillips, F.R.S.; Tuesdays and Saturdays, at a quarter past eleven. Single course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

Botany; first course, 1*l.* 1*s.*; perpetual, 2*l.* 2*s.*

Medical Practice; physician's pupil, two years, 24*l.* 3*s.*; one year, 15*l.* 15*s.* The physicians make their visits daily, at one o'clock; Dr. Williams on Mondays and Thursdays; Dr. Elliotson on Tuesdays and Fridays; Dr. Roots on Wednesdays and Saturdays; Dr. Burton sees the out-patients on Thursdays and Saturdays at eleven. Clinical lectures will be delivered to the physicians' pupils by Dr. Elliotson and Dr. Roots.

N.B. The Apothecaries' Hall requires candidates to attend the following courses of lectures:

Chemistry, two courses, each course consisting of not less than forty-five lectures.

Materia Medica and Therapeutics, two courses, each course consisting of no less than forty-five lectures.

Anatomy and Physiology, } two courses,
Anatomical Demonstrations, }
of the same extent as required by the Royal College of Surgeons, of London.

Principles and Practice of Medicine, two courses, each course consisting of not less than forty-five lectures, to be attended subsequently to the first course of lectures on chemistry, materia medica, and anatomy and physiology.

Botany, one course.

Midwifery and the Diseases of Women and Children, two courses; *Forensic Medicine*, one course, to be attended during the second year.

And twelve months*, at least, the Physician's practice at a hospital (containing not less than sixty beds,) such attendance to commence the second year.

Students are moreover recommended diligently to avail themselves of instruction in *morbid anatomy*, and to attend *clinical lectures*.

Anatomy, Physiology, and Operations of Surgery; Mr. Tyrrell, and Mr. John F. South, daily, at half-past two o'clock. Lectures; first course, 5*l.* 5*s.*; second course, 4*l.* 4*s.*; perpetual, 10*l.* 10*s.* Dissections and demonstrations; first course, 5*l.* 5*s.*; second course, 4*l.* 4*s.*; perpetual, 10*l.* 10*s.*

Anatomical Demonstrations; Mr. S. Solly, Mr. B. Travers and Mr. Clark, daily, at nine o'clock.

Principles and Practice of Surgery; Mr. Tyrrell, Mondays, Wednesdays, and Fridays, at seven in the evening. Single course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

Surgical Practice; dresser, one year, 5*l.* 2*s.*; six months, 3*l.* 12*s.*; surgeon's pupil, one year, 26*l.* 6*s.*; six months, 20*l.* 0*s.*; a second entry, if within two months, 6*l.* 12*s.*

The surgeons make their visits daily; Mr. Travers on Mondays and Thursdays at one o'clock; Mr. Green on Tuesdays and Fridays at one o'clock; Mr. Tyrrell on Wednesdays and Saturdays at half-past eight o'clock, A. M.; Mr. Tyrrell sees the out-patients on Wednesdays at eight o'clock; on Fridays operations are performed.

Clinical lectures will be given to the dressers, and surgeons' pupils, by Mr. Green and Mr. Tyrrell. Pupils entering to the surgical practice of St. Thomas's hospital, are allowed to attend that of Guy's.

N.B. The College of Surgeons requires candidates to bring proof, 1, of being twenty-two years of age; 2, of having been engaged six years in the acquirement of professional knowledge; 3, of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons*; 4, of having attended at

least two courses of lectures on surgery, delivered at two distinct periods or seasons, each course to comprise not less than sixty lectures; 5, of having attended lectures on the practice of physic, on chemistry, and on midwifery during six months; and on botany and materia medica during three months; 6, of having attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals and twelve months in any recognised provincial hospital.

Mr. Whitfield, apothecary to St. Thomas's hospital, is empowered to enter gentlemen who may wish to attend any of the above lectures, or the practice of the hospital.

Library. Gentlemen who enter to the practice or the lectures at this hospital are allowed the use of the library and of the reading-room, so long as they continue attending as pupils, on the payment of one guinea.

LONDON HOSPITAL.

LECTURES.

Principles and Practice of Medicine; Dr. Billing and Dr. Davis. Winter division, Tuesdays, Thursdays, and Fridays, at half-past three. Spring division, Tuesdays, Thursdays, and Saturdays, at eight P. M. One course, 4*l.* 4*s.*; two courses, 6*l.* 6*s.*; perpetual, 7*l.* 7*s.*

Materia Medica and Therapeutics; Dr. Cobb, Wednesdays and Fridays, at nine A. M. One course, 3*l.* 3*s.*; two courses, 4*l.* 4*s.*; perpetual, 4*l.* 4*s.*

Midwifery, and Diseases of Women and Children; Dr. F. H. Ramsbotham, Tuesdays, Thursdays, and Saturdays, at ten A. M. One course, 3*l.* 3*s.*; two courses, 5*l.* 5*s.*; perpetual, 7*l.* 7*s.*

Chemistry, General and Pharmaceutic; Mr. Pereira, Mondays, Wednesdays, and Fridays, at ten A. M. One course, 4*l.* 4*s.*; two courses, 7*l.* 7*s.*; perpetual, 8*l.* 8*s.*

Medical Jurisprudence; Dr. Cobb, Dr. F. H. Ramsbotham, and Mr. Pereira, Saturdays, at half-past three. One course, 3*l.* 3*s.*; two courses, 4*l.* 4*s.*; perpetual, 4*l.* 4*s.*

Anatomy, Physiology, and Operations of Surgery; Mr. Luke, Mr. Hamilton, and Mr. Adams, daily, at half-past two. One course, 5*l.* 5*s.*; two courses, 9*l.* 9*s.*; perpetual, 10*l.* 10*s.*

Surgery, Principles and Practice of; Mr. John Scott, Mondays and Wednesdays, at se-

extend from October to April inclusive, and to comprise at least 140 lectures on anatomy and physiology, occupying not less than one hour each, given on separate days; and at least 100 demonstrations of the like duration, given in a similar manner; exclusive of dissections, of which distinct certificates are required.

* An anatomical season is understood to

ven p.m. One course, 3*l.* 3*s.*; two courses, 5*l.* 5*s.*

Anatomy, Practical with Demonstrations; Mr. Hamilton and Mr. Adams, daily, at a quarter-past eleven. One course, 3*l.* 3*s.*; two courses, 6*l.* 6*s.*; perpetual, 10*l.* 10*s.*

One of the demonstrators daily attends in the dissecting room, from eleven to four.

Botany, Medical and General; Mr. Pereira. One course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 3*l.* 3*s.*

General fee for attendance upon all the above lectures, qualifying for Royal College of Surgeons and Apothecaries' Hall, 50*l.*

Phrenology; with Gall and Spurzheim's views of the brain, human and comparative, by Mr. H. Haley Holm.

Hospital Practice; physicians, Dr. Frampton, Dr. Billing, Dr. Gordon; surgeons, Sir William Blizard, Mr. Andrews, Mr. John Scott.

Physicians' pupil, twelve months, 10*l.* 10*s.*; perpetual, 21*l.*; apothecaries' fee, 1*l.* 1*s.*; surgeons' pupil, twelve months, 21*l.*; ditto as dressing pupil, 31*l.* 10*s.*; six ditto ditto, 21*l.* library, 1*l.* 1*s.*

Clinical Lectures by the physicians and surgeons.

ST. GEORGE'S HOSPITAL.

The following courses of lectures (which are not restricted to the pupils of the hospital) will be given during the winter season, commencing October 1st.

Theory and Practice of Physic, by Dr. Chambers and Dr. Macleod, on Monday, Wednesday, and Friday, at half-past eleven. Each course, separately, 3*l.* 3*s.*; two courses, at one payment, 5*l.* 5*s.*; perpetual, 6*l.* 6*s.*

Theory and Practice of Surgery, by Mr. Cæsar Hawkins and Mr. G. Babington, on Monday, Wednesday, and Friday, at eight in the evening. Each course, lasting the whole season, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

Materia Medica, by Dr. Macleod and Dr. Seymour, on Tuesday, Thursday, and Saturday, at half-past eleven. Each course, separately, 3*l.* 3*s.*; two courses, at one payment, 5*l.* 5*s.*; perpetual, 6*l.* 6*s.*

Midwifery, and the Diseases of Women and Children, by Mr. Stone, conjointly with Dr. Henry Davies, on Monday, Wednesday, and Friday, at nine. Each course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

Medical Jurisprudence, by Dr. Seymour and Mr. Cæsar Hawkins, on Tuesdays and Thursdays, at half-past seven in the evening. Each course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

Botany, by Dr. Dickson, on Tuesday, Thursday, and Saturday, at a quarter to four; one half of the course being given in October, and the other half in April. One course, 3*l.* 3*s.* perpetual, 4*l.* 4*s.*

Physicians' pupils admitted to attend the practice of the physicians; for nine months, to pay 12*l.* 12*s.*; for one year, 16*l.* 16*s.*; per-

petual pupils, 25*l.* 4*s.* Every pupil, on admission, is to pay one guinea to the apothecary. Clinical lectures are given gratuitously to the pupils of the hospital, by Dr. Seymour and Dr. Wilson; and lectures on pathology by Dr. Wilson, of which notice will be given.

Surgeons' pupils admitted to attend the practice of the surgeons; for six months, to pay 15*l.* 15*s.*; for one year, 21*l.*; perpetual, 52*l.* 10*s.* Pupils entering for twelve months are allowed to dress the patients for three months without additional fee; the perpetual pupils are entitled to dress twice, and also to be house surgeons, when properly qualified for the office.

Clinical lectures are given gratuitously to the pupils of the hospital by Mr. Hawkins and Mr. Babington, of which notice will be given.

Reception of patients on Wednesdays; operations on Thursdays, at one o'clock.—The physicians and surgeons attend almost daily at half-past twelve.

THEATRE OF ANATOMY, Adjoining St. George's Hospital.

Two courses of lectures will be delivered by James Arthur Wilson, M.D., Fellow of the Royal College of Physicians, and one of the Physicians of St. George's Hospital; and by Mr. Samuel Lane, Member of the Royal College of Surgeons.

These lectures will embrace a complete system of *Anatomy, Physiology, Pathology, and Surgical Anatomy*. The healthy structure of the human body will be fully described in each of the two courses. Its functions and uses, with the changes to which it is subjected by disease, will be more particularly considered in the second course.

At the close of the spring course, the *Operations of Surgery* will be performed and explained.

The first course will commence on Tuesday the 1st of October, and will terminate in the middle of January. The second course will commence on the 20th of January, and terminate early in May.—A lecture will be given daily, at half-past two o'clock.

DISSECTIONS AND DEMONSTRATIONS.

Two courses of *Demonstrations* will be delivered by Mr. Lane and Mr. Harrison, Members of the Royal College of Surgeons.

The dissections will commence on the 10th of October, and will be continued till the last week in April.

A Demonstration will be given every morning, at half-past ten o'clock.

Terms of the Lectures.—First course, 4*l.* 4*s.*; each succeeding course, 3*l.* 3*s.*; perpetual, 8*l.* 8*s.* A pupil having attended three courses will be considered as perpetual.

Terms of the Dissections and Demonstrations.—First course, 4*l.* 4*s.*; each succeeding course, 3*l.* 3*s.*; perpetual, 8*l.* 8*s.* A pupil

having attended three courses will be considered as perpetual.

Further particulars may be obtained from Dr. Wilson, No. 38, Curzon-street, May-Fair; from Mr. Lane, No. 1, Grosvenor-place; and from Mr. Harrison, 25, Argyll-street.

THEATRE OF ANATOMY AND MEDICINE,

Webb-street, Maze Pond, Borough.

The winter courses of lectures, to be delivered at this theatre, will be commenced on Tuesday, October 1st, 1833.

Anatomy and Physiology; Mr. Grainger and Mr. Pilcher; daily at half-past two o'clock.

Mr. Grainger will deliver the introductory lecture at a quarter past eleven on Tuesday, October 1st.

Demonstrations on Anatomy; Mondays, Tuesdays, Thursdays, and Fridays, at a quarter past eleven, A.M.; Mr. C. Millard. Terms: Lectures and demonstrations; single course, 5*l.* 5*s.*; two courses, 8*l.* 8*s.*; perpetual, 10*l.* 10*s.* Dissections as usual, by the lecturers and demonstrator.

Principles and Practice of Surgery; Mr. Grainger and Mr. Pilcher, Mondays, Wednesdays, and Fridays, at six in the evening.

Mr. Pilcher will deliver the introductory lecture on Wednesday, October 2nd. Terms: One course, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.*

Chemistry; Mr. Cooper, Mondays, Wednesdays, and Fridays, at a quarter before ten in the morning. Terms: Single course, 4*l.* 4*s.*; second and every succeeding course, 2*l.* 2*s.*; two courses entered together, 5*l.* 5*s.*; perpetual, 6*l.* 6*s.*

Principles and Practice of Midwifery, and the Diseases of Women and Children; Dr. Robert Lee, F.R.S., Tuesdays, Thursdays, and Saturdays, at five o'clock in the afternoon.

The introductory lecture will be delivered on Tuesday, the 1st of October. Terms: Single course, 3*l.* 3*s.*; two courses entered together, 5*l.* 5*s.*; perpetual, 6*l.* 6*s.*

The great advantage to be derived from these lectures will be, the extensive field of practical instruction which Dr. Lee has it in his power to lay open to his students, and the very frequent opportunities each of them will have of attending cases under his own superintendence.

The museum will be open several hours every day for the admission of students.

N.B. The regulations of the Council of the Royal College of Surgeons require candidates for examination to have attended the following lectures:—

Anatomy and Demonstrations, during two anatomical seasons.

An anatomical season is understood to extend from October to April inclusive.

Principles and Practice of Surgery, two courses.

Practice of Physic, two courses.

Chemistry, two courses.

Midwifery, two courses.

Botany, one course.

Materia Medica, one course.

The candidate must also have attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital.

It is earnestly recommended that candidates shall have studied anatomy, by attendance on lectures and demonstrations, and by dissections, for one anatomical season prior to their attendance on the surgical practice of an hospital.

Theory and Practice of Medicine; Dr. Whiting, Mondays, Wednesdays, and Fridays, at a quarter before four o'clock in the afternoon.

The introductory lecture will be delivered on Wednesday, October 2nd. Terms: One course, 4*l.* 4*s.*; second course, 3*l.* 3*s.*; two courses, or perpetual, at one entry, 6*l.* 6*s.*

The first few lectures will be occupied by an elementary view of the healthy and disordered functions of the human body, such as may tend to prepare the pupil for his future studies.

Materia Medica, Pharmacy, and Therapeutics; Dr. Whiting and Mr. Everitt, Tuesdays, Thursdays, and Saturdays, at a quarter before ten in the morning.

The introductory lecture will be delivered on Tuesday, October 1st. Terms: One course, 3*l.* 3*s.*; perpetual, 6*l.* 6*s.*

The lectures on materia medica, &c. will be illustrated by chemical experiments, by specimens of drugs, and by dried plants and botanical plates. A cabinet is likewise fitted up with good and bad specimens of every medicine now in use, which will be open to the inspection of those students who attend these lectures.

Botany; Dr. Robert Dickson, F.L.S. During October and April, Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays, at seven, P.M. Terms: One course, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

The introductory lecture will be delivered on Tuesday, October 1st.

Medical Jurisprudence; Dr. Southwood Smith and Mr. Cooper, Tuesdays and Thursdays, at six in the evening. Terms: One course, 3*l.* 3*s.*; two courses, 4*l.* 4*s.*; perpetual, 5*l.* 5*s.*

Gentlemen entering to this course have the privilege of attending gratuitously the practice of the London Fever Hospital.

Periodical examinations will be given by the different lecturers in their various departments.

N.B. The regulations of the Court of

Examiners of the Apothecaries' Hall require candidates for examination to have attended the following lectures:—

Chemistry, two courses.

Materia Medica and Therapeutics, two courses.

Anatomy and Physiology, two courses.

Anatomical Demonstrations, two courses.

Principles and Practice of Medicine, two courses. The first course on this subject to be attended subsequently to the termination of the first course of lectures on chemistry, materia medica, and anatomy and physiology*.

Botany, one course.

Midwifery, and the Diseases of Women and Children, two courses.

Forensic Medicine, one course; to be attended during the second year.

Students are moreover recommended diligently to avail themselves of instruction in morbid anatomy.

The candidate must also have attended for twelve months, at least, the physician's practice at an hospital containing not less than sixty beds, and where a course of clinical lectures is given; or for fifteen months at an hospital wherein clinical lectures are not given; or for fifteen months at a dispensary connected with some medical school recognised by the court. The whole of such attendance to be subsequent to the first year of attendance on lectures.

The meetings of the Webb-street Medical Society are held every Saturday evening, at a quarter before eight. Gentlemen entering to this school are eligible to become members of the Society, to which is attached a library, on the payment of the annual sum of five shillings.

For further information apply at the Theatre; to Mr. Grainger, at Mr. Highley's Medical Library, adjoining the Theatre; Mr. Pilcher, 5, Union-street, Borough; Mr. Cooper, 9, Paradise-street, Lambeth; Dr. Lee, 14, Golden-square; Dr. Whiting, Wellington-street, Borough, or 13, Rodney-buildings, New Kent-road; Mr. Everitt, 28, Golden-square; Dr. Southwood Smith, 36, New Broad-street; Dr. Dickson, 47, Finsbury-square; Mr. Millard, 28, Dean-street, Borough; Mr. Highley, Medical Bookseller, 32, Fleet-street, opposite St. Dunstan's Church; or Messrs. MacLachlan and Stewart, Booksellers, Edinburgh.

* * * Mr. Highley is authorised to enter gentlemen to the above lectures.

THEATRE OF ANATOMY.

Little Windmill Street, Golden Square.

The following lectures will be delivered at this Theatre. The Autumnal course to com-

* This regulation is not intended to prohibit gentlemen from taking a perpetual ticket at the commencement of the session, but only requires that two courses of the common length should be attended after one course of anatomy, chemistry, &c.

mence October 1st, 1833; Spring course, January 20th, 1834.

Anatomy, Physiology, with Demonstrations and Dissections; Mr. E. W. Tuson.

The Principles, Practice, and Operations of Surgery; Mr. Guthrie.

Clinical lectures on surgery will be delivered occasionally by Mr. Guthrie at the Westminster Hospital, and on the diseases of the eye at the Royal Westminster Ophthalmic Hospital.

Practice of Physic and Materia Medica; Dr. Sigmond.

Chemistry; Mr. Everitt.

Midwifery, and the Diseases of Women and Children; Dr. Jewell.

Medical Jurisprudence; Dr. Sigmond, Dr. Jewell, and Mr. Everitt.

Botany; Mr. Harding.

* * * This Theatre is situated about a quarter of an hour's walk from St. George's, the Middlesex, and Westminster Hospitals.

For further particulars apply to Mr. Tuson, No. 10, Russell Place, Fitzroy Square, or to either of the lecturers.

WESTMINSTER SCHOOL OF MEDICINE,

No. 2, Princes's Street, Storey's Gate, St. James's Park.

Anatomy and Physiology; demonstrations and dissections, Mr. Dobson. One course, 3*l.* 3*s.*; perpetual, 7*l.* 7*s.*

Materia Medica and Botany; Dr. Epps. One course, 2*l.* 2*s.*; perpetual to these and to chemistry, 7*l.* 7*s.*

Chemistry; Dr. Epps, assisted by Mr. Crump. One course, 3*l.* 3*s.*

Practice of Physic; Dr. Weatherhead. One course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

Midwifery; Dr. Ryan. One course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

Medical Jurisprudence; Dr. Ryan and Mr. Crump. One course, 2*l.* 2*s.*; two courses, 3*l.* 3*s.*; perpetual, 4*l.* 4*s.*

The introductory lecture will be delivered by Dr. Epps, on Tuesday, October 1st, at six o'clock in the evening.

Anatomy and Physiology. A demonstration on the dead subject will be delivered every morning, and when the minute structures are unable to be shown on the recent subject, they will be illustrated by preparations.

The afternoon lectures will be occupied almost exclusively in considering the development of the different tissues, structures, and organs; together with a comprehensive course of physiology. Many of the important physiological experiments will be performed in the presence of the class; such as the relative periods at which blood coagulates; the circulation of the chyle in the lacteals; the phenomena of digestion, &c.

Two courses will be delivered during the winter session, and the last week of each

course will be occupied in showing on the dead body the various surgical operations, more especially the minor.

The best methods of applying bandages, and the mode of preparing and preserving specimens of natural and morbid structures will be taught.

Mr. Dobson has made such arrangements as will enable him to obtain an ample supply of subjects.

Chemistry, Materia Medica, and Botany. Dr. Epps, in his lectures on chemistry, will comprise practical and toxicological chemistry, in which the pupils will make the various chemicals, and test and analyse the various poisons.

Dr. Epps considers that this mode of instruction is the one best calculated to enlarge the mind, and to bring the student into intimate acquaintance with the weapons he has to use in combating the diseases to which the human being is liable.

Dr. Epps further requests his pupils to give weekly reports to him in writing of his lectures, which Dr. E. corrects and returns. This plan, combined with that of catechetical instruction, has been very successful in making good chemists and good materia medics. Dr. E. has a museum, both chemical and botanical, as well as one appropriated to the articles of the materia medica. In regard to the mode to be adopted in the study of the materia medica, Dr. E. will investigate the natural, chemical, pharmaceutical, and medical characters of each article; this will occupy the whole of the first course. In the second course, these articles of the materia medica will be grouped into classes, and considered under this arrangement.

By such modes of investigation, it is hoped that a perfect knowledge will be obtained of all the characters belonging to each, and every article of the materia medica; and choice specimens will be exhibited of each article.

Principles and Practice of Medicine. In the course of lectures which will be delivered on the principles and practice of medicine by Dr. Hume Weatherhead, the lecturer, shunning the unstable foundations of theoretical speculation, will make it a main object of his study to direct the attention of medical students to doctrines that are strictly practical, illustrating his subject in all its multifarious forms, by selecting, as occasions may offer, the opinions of the most approved writers on the various diseases to be treated of. The lecturer will further illustrate his subjects by placing under the review of his pupils the different opinions that may have been entertained by writers of every age, whenever these may be deemed instructive and useful. At the same time that he is aware of the overweeningness so apt to beset a lecturer in favour of his own particular views, Dr. W. will strive to guard against this weakness; and by impartially propounding the opinions of others, put the student's judgment into such a com-

prehensive position as shall enable him to judge correctly, and to arrive at the safest and soundest practical conclusions.

The introductory lecture to the course will comprise a succinct history of medicine, from the earliest ages to the present period.

Midwifery or Obstetrics. Dr. Ryan's lectures on midwifery or obstetrics include the fullest consideration of the diseases of women and children, with a description of the management of every species of parturition hitherto recorded. Weekly examinations are held, and an abundant supply of obstetric cases afforded pupils. The course is divided as follows:—first division, gynecology, history of woman; gynecotomy, anatomy of; gynæphysiology, physiology of; gynecology, history of reproduction; embryology, physiology of the embryo; tocology, parturition; eutocia, natural labour. Second division, gynæcopathology, pathology of women, including parthenosology, diseases of virgins; encyonosology, diseases of pregnant women; dystocia, difficult or morbid parturition; chiragotocia, manual parturition; organigotocia, instrumental parturition; lochionosology, diseases of puerperal women; pædonosology, physical education and diseases of children.

Medical Ethics and Jurisprudence. Dr. Ryan will adopt the comprehensive system of foreign schools in his lectures on medical jurisprudence, by adopting the following plan:—introductory, medical economy and ethics, education, distinctions, rights, privileges, immunities of the faculty, qualifications for professor and lectureships, hospital and other officers, moral or ethical department of medical practitioners in public and private practice. First division. Duties of the medical profession in co-operation with the legislature, government and magistracy for the conservation of public health, and for legislation relating to the practice of the profession. These topics constitute public, political and state medicine, public hygiene, police of health, or medical police. This department embraces age, physical education, when crime can be committed, marriage and population, impotence, sterility, hermaphrodites, monsters, divorce, fecundity, mortality; air, aliment, their adulterations, contagious and epidemic diseases, precautionary measures, quarantine, diseases incidental to certain trades, temporary hospitals, boards of health, medical legislation.

Second division. Medical jurisprudence, legal, forensic, juridical or judiciary medicine, or the application of medicine and its collateral sciences to the elucidation of civil and criminal proceedings during judicial inquiries. Arrangement of the subject according to Blackstone, medico-legal questions relating to the morals, and the reproduction of the species; defloration, marriage, uterogestation or pregnancy, verification of, duration of, legitimacy, abortion, parturition or delivery, policide or infanticide. Attempts against health and life, maiming, mutilating, homi-

cide, duelling, suicide, persons found dead; coroner's inquests, duties of medical witnesses, autopsies or post mortem examinations, homicide by suffocation, drowning, hanging, choking, smothering, irrespirable gases, torrefaction, combustion or burning, cold, starvation. Poisoning, including the science of toxicology, or the history, action, treatment, and detection of every known poison; this last illustrated by experiments, casts, and drawings. Mental alienation, idiocy, imbecility, mania, monomania, dementia, legal and medical definitions of, civil and criminal responsibility, lucid intervals, execution of bonds and wills, medical certificates, actions for, responsibility of drunkards, epileptics, hysterics, somnambulists, and those subject to violent fits of passion. Competency of deaf, dumb, and blind to execute deeds, bonds, and wills. Simulated or feigned diseases, as in cases of soldiers, sailors, prisoners; dissimulated or concealed diseases; pretended, when an advantage, revenge, or escape of punishment is the object; imputed when no disease exists, but when property is to be gained. Disqualifying diseases in cases of jurors, witnesses, soldiers, &c. for hard labour, flogging, treadmill; mode of examining recruits; impostures, estimation of insurability of life; diseases which affect policy, exceptions, suicide, duelling, or dying by the hands of justice. Medical evidence, law on dying declarations, hearsay evidence, when admissible—confession of accused; conduct of medical practitioners in all these cases. Lastly, forms of certificates for exempting jurors, witnesses, soldiers, persons proposing to insure their lives in cases of insanity, &c. &c.

The medical and surgical part of this course will be delivered by Dr. Ryan; and the toxicological by Mr. Crump, both of which will be illustrated by drawings, preparations, and experiments.

MEDICAL SCHOOL,

58, Aldersgate Street,

Contiguous to St. Bartholomew's Hospital.

The several courses of lectures will commence on Tuesday the 1st of October, 1833.

Anatomy and Physiology; by Robert B. Todd, M.B., Candidate of the Royal College of Physicians, London; Mr. Skey, Assistant-surgeon to St. Bartholomew's Hospital; and Mr. J. H. Walsh.

The lectures will be delivered daily at half-past two o'clock. They will comprise a complete course of anatomy, medical and surgical.

In the second division of the course, surgical anatomy and surgical operations will be given. This portion of the lectures will be undertaken by Mr. J. H. Walsh.

The Anatomical Demonstrations; daily, at nine A.M., by Mr. Skey, who will personally superintend the dissections of the students, in conjunction with Dr. Todd and Mr. Walsh.

Terms: lectures, first course, 3l. 3s.; second course, 6l. 6s.; perpetual, 7l. 7s.; demonstrations and dissections, first course, 3l. 3s.; second course, 5l. 5s.; perpetual, 7l. 7s.; perpetual entry to the anatomical lectures, demonstrations, and dissections, 12l. 12s.

For further particulars apply to Dr. Todd, 5, Hart-street, Bloomsbury; Mr. Skey, 33, Southampton-row, Russell-square; or at the school.

Principles and Practice of Medicine; by John Burne, M.D., Physician to the Public Dispensary, Chancery-lane, will be delivered on Tuesdays, Thursdays, and Saturdays, at eight o'clock in the evening.—Terms: One course, 3l. 3s.; perpetual, 5l. 5s.

These lectures will comprise general and special morbid anatomy, a comprehensive view of the principles of the practice of medicine, and a detailed account of the nature and treatment of special or individual diseases.

Dr. Burne will also deliver lectures on the principles and practice of medicine, at his residence, 24, Spring Gardens, Charing-cross, on Tuesdays, Thursdays, and Saturdays at six o'clock in the evening.

For further particulars apply at the school, or to Dr. Burne, 24, Spring Gardens, Charing-cross, from nine to twelve o'clock in the morning.

SCHOOL OF MEDICINE, WESTMINSTER DISPENSARY,

Gerrard-street, Soho.

The following lectures at this school will commence on Wednesday, Oct. 2nd.

Chemistry, Materia Medica, and Botany, by Dr. Epps, assisted by Mr. Crump.

Medicine, Midwifery, and Medical Jurisprudence, by Dr. Ryan.

Toxicological Chemistry, by Mr. Crump.

For further particulars apply to Dr. Ryan, 61, Hatton Garden, Dr. Epps, 89, Great Russell-street, or to Mr. Crump, Bernard-street, Russel-square.

HUNTERIAN THEATRE OF ANATOMY,

Great Windmill Street, Haymarket.

Lectures on Anatomy, Physiology, Pathology, and Surgery, by Mr. John Gregory Smith and Mr. Richard Bushell, formerly house surgeons of St. George's Hospital.

Two courses of lectures are given during the winter season, one of which commences on Tuesday, the 1st of October, and terminates towards the middle of January; the second commences on the 20th of January, and terminates early in May.

Each course of lectures comprehends a full description of the healthy structure and functions of the human body, and an outline of the phenomena of disease, illustrated by recently dissected parts, and by preparations.

At the close of the second course the operations of surgery are shown.—A lecture will be given daily, at half-past two o'clock.

DISSECTIONS AND DEMONSTRATIONS.

The rooms are opened for dissection from the 8th of October to the 1st of May; during this period an *Anatomical Demonstration* will be given daily, and examinations held twice a-week.

Mr. Smith and Mr. Bushell will attend in the dissecting room during the day, and afford assistance to those students who may require it.

The museum will be open to the pupils on all occasions, and every facility afforded for their becoming acquainted with the art of *injecting and making preparations of healthy and morbid structure*.

Terms of the Lectures.—First course, 3l. 3s.; perpetual, 6l. 6s.

Terms of the Dissections and Demonstrations.—First course, 3l. 3s.; perpetual, 6l. 6s.

Mr. Smith and Mr. Bushell take this opportunity of stating, that the lectures and dissecting rooms will be open, free of expense, to the perpetual pupils of the former school at this theatre, and to the perpetual pupils of the late school of Joshua Brooks, Esq. F.R.S. &c. &c. A personal application is required.

Gentlemen residing in town, or established in practice, may be accommodated with private and airy rooms for dissections, replete with every convenience.

Mr. Bushell will be happy to give private instruction and examinations in the evening to gentlemen who may wish to avail themselves of the opportunity, previous to their examinations at the Royal College of Surgeons, &c.

A summer course of lectures on Anatomy, Physiology, and Surgery, will commence in June, and the dissecting rooms will be open during a part of the season.

Further particulars may be known on application to Mr. Smith or Mr. Bushell, and at the Anatomical Theatre between the hours of ten and four.

THEATRE OF ANATOMY AND SURGERY,

OF THE LATE JOSHUA BROOKES, F.R.S.

This School will be re-opened on the 1st of October next.

Anatomy, Physiology, and Morbid Anatomy; Mr. King and Mr. Malyn.

Demonstrations and Dissections, under the direction of Mr. Malyn.

Surgery and Surgical Operations; Mr. King.

For particulars and a prospectus of the plan of teaching, apply to Mr. King, Hanover-street, Hanover-square, and Mr. Malyn, Duke-street, Westminster.

CENTRAL SCHOOL OF MEDICINE AND SURGERY,

St. George's and St. James's Dispensary, No. 60, King Street, Golden Square.

The following lectures will be delivered at this school, commencing on Wednesday, Oct. 2, 1833:—

Principles and Practice of Medicine; by Dr. G. Gregory.

Materia Medica and Therapeutics; by Dr. Webster.

Principles and Practice of Surgery; by J. F. Palmer, Esq.

Forensic Medicine; by Dr. J. Wyatt Crane.

Midwifery and the Diseases of Women and Children; by Dr. Ashburner and Dr. Chowne.

Botany; by Dr. Macreight (to commence 1st of April, 1834).

The medical practice of the dispensary (recognised by the Apothecaries' Company) and the surgical practice are also open for the admission of pupils.

Physicians.—Dr. Webster and Dr. J. Wyatt Crane.

Surgeons.—John Bacot, Esq., and J. F. Palmer, Esq.

A prospectus of the lectures, with full particulars of the terms and hours of attendance, may be had at Burgess and Hill's, 55, Great Windmill Street, and at the dispensary, No. 60, King Street, Golden Square.

SCHOOL OF ANATOMY AND MEDICINE,

No. 18, Giltspur Street, adjoining St. Bartholomew's Hospital.

The lectures at this school commence on Tuesday, Oct. 1st, 1833.

Theory and Practice of Medicine; by Dr. Tweedie, on Mondays, Wednesdays, and Fridays, at eight o'clock in the evening.

Chemistry; by Mr. James L. Wheeler, on Mondays, Wednesdays, and Fridays, at half-past three o'clock in the afternoon.

Materia Medica, Botany, and Practical Toxicology; by Mr. James L. Wheeler, on Tuesdays, Thursdays, and Saturdays, at half-past three o'clock in the afternoon.

Anatomical Demonstrations and Dissections; by Mr. Lowe Wheeler, daily, at ten o'clock in the morning.

Midwifery and the Diseases of Women and Children; by Dr. Millar, on Mondays, Wednesdays, and Fridays, at a quarter before six o'clock in the evening.

Forensic Medicine; by Mr. Barnes, on Tuesdays and Thursdays, at seven o'clock in the evening.

For particulars, application may be made to Mr. Wheeler, at the lecture room; to Dr. Tweedie, No. 30, Montague Place, Russell Square; or to Dr. Millar, No. 3, New Basinghall Street.

WESTERN DISPENSARY,*Charles Street, Parliament Street.*

Dr. Clendinning and Dr. Burke will deliver the introductory lectures to their courses on the practice of physic and materia medica, at the Dispensary on the 1st of October.

In addition to these courses will be delivered, by the same gentlemen, lectures on clinical and on forensic medicine.

Perpetual pupils to the dispensary will be entered to all these lectures on payment of three guineas, in addition to the fee paid for attendance on the practice of the charity.

Certificates for the above lectures will be received at the College of Surgeons and Apothecaries' Hall.

SAMUEL DUNN, *Apothecary.*

Dispensary, Sept. 4th, 1833.

Dr. COLLIER's Winter course of lectures on the theory and practice of physic, and on materia medica, will commence on Monday, October the 14th, at five o'clock P.M.

Dr. Collier continues to receive private and house pupils as heretofore.

32, Spring Gardens.

GENERAL DISPENSARY,*36, Aldersgate Street.*

Mr. Pereira will commence the Autumnal courses of lectures on general and pharmaceutical chemistry and on materia medica, on Tuesday, October 1st, at ten o'clock in the morning, at the General Dispensary, 36, Aldersgate-street.

For prospectuses and further particulars apply to Mr. Pereira, at his residence, 151, Aldersgate-street.

Dr. ROBERTS, lately one of the Physicians to the General Dispensary, Aldersgate-street, will commence his autumnal course of lectures upon the Theory and Practice of Medicine, at Dr. Waller's Lecture Room, 93, Bartholomew Close, near to St. Bartholomew's Hospital, on Wednesday, the 2nd of October, at half-past four o'clock in the afternoon.

Particulars may be obtained of Dr. Waller, 93, Bartholomew Close; or of Dr. Roberts, 31, New Bridge-street.

LECTURES ON PHYSIOLOGY.

R. E. Grant, M.D., F.R.S.E., Fellow of the Royal College of Physicians of Edinburgh, Member of the Medical Faculty of the University of London, &c., will commence his practical course of human physiology, on the 1st of February next, at his house, 10, Seymour-place North, Euston-square.

The hour will be announced hereafter.

MIDWIFERY, AND THE DISEASES OF WOMEN AND CHILDREN.

Mr. Morley, Surgeon-Accoucheur of the

Farringdon Lying-in Charity, continues to lecture upon the above-mentioned subjects, on Tuesdays and Thursdays, from seven till eight o'clock in the evening. — Terms: For one course, 3*l.* 3*s.*; for an unlimited privilege, 4*l.* 4*s.*

The next course will be commenced on Tuesday the 8th of October.

Further particulars may be obtained at the Institution, 5, Ball-court, Giltspur-street, near St. Bartholomew's Hospital, and of Mr. Morley, at his residence, No. 100, Hatton-garden.

NATIONAL GALLERY OF PRACTICAL SCIENCE,*Adelaide St., Lowther Arcade, West Strand.*

Mr. Maugham's Winter course of lectures on general and pharmaceutical chemistry and materia medica will commence at the above Institution on Tuesday, October 1st, 1833, at eight o'clock in the evening, and will be continued every Tuesday, Thursday, and Saturday at the same hour.

The arrangement of these lectures consists in first noticing the properties of matter, and the laws by which chemical action is maintained. After having considered the imponderable bodies, a description of the elementary ponderable bodies, and their several combinations with each other, will follow:—the classification is such as not to bring under observation, in a compound substance, any element that has not previously been spoken of. The different classes of salts, resulting from the union of the acids and bases already described will then be noticed. Vegetable and animal chemistry will next be considered. The preparations of the pharmacopœia, and the articles of the materia medica, and the different tests for poisons, as well as the mode of conducting analyses, will be particularly dwelt upon in their several orders in the course, and the whole will be experimentally illustrated with extensive apparatus, and specimens of materia medica, &c. &c.

The proprietors venture to state, that the apparatus relating to electro-magnetism, and the new branch of science termed magneto-electricity, will be found superior to any, either in this country or on the continent.

Terms: One course of chemistry and materia medica, 4*l.* 4*s.*; two courses paid for at once, rendering a pupil perpetual, 6*l.* 6*s.*

Certificates of Mr. Maugham's lectures are received at the College of Surgeons and Apothecaries' Hall.

These lectures will be accompanied with examinations; and the pupils will have an opportunity of going through a series of experiments at stated periods during the session.

Perpetual pupils will have free admission to the National Gallery of Practical Science.

For further particulars inquire of Mr. Payne, at the Gallery, from ten till four, who is authorised to enter pupils.

A course of lectures on chemistry as applied

to the arts, will shortly commence at the above Institution, by Mr. Maugham, of which due notice will be given to the public.

MIDDLESEX HOSPITAL.

SURGEONS' DRESSERS AND PUPILS.

Dresser for twelve months, 31*l.* 10*s.*; for six months, 21*l.*

Pupil for twelve months, 21*l.*; for six months, 15*l.* 15*s.*; for three months, 10*l.* 10*s.*

From the dressers the house surgeon is elected, agreeable to his date of entrance.

A pupil may be allowed three months' dressings, during the time of his pupilage, by paying 10*l.* 10*s.*

MEDICAL PRACTICE.

During three months, 6*l.* 6*s.*; six months, 10*l.* 10*s.*; nine months, 12*l.* 12*s.*; twelve months, 15*l.* 15*s.*; unlimited attendance, 22*l.* 1*s.* Apothecaries' fee, 1*l.* 1*s.*

Clinical Lectures are delivered gratuitously to the physicians' pupils.

WESTMINSTER HOSPITAL,

MEDICAL PRACTICE.

During six months, 10*l.* 10*s.*; nine months, 12*l.* 12*s.*; twelve months, 15*l.* 15*s.*; unlimited attendance, 21*l.*

A *Clinical Lecture* will be given twice a week during the Winter months.

On the 1st of November and 1st of May, in each year, a clinical assistant to the physicians will be elected, by examination, for the ensuing six months; for this office, which affords many advantages, any pupil may become a candidate after he has diligently attended the physicians' practice for three months. If a physician's pupil should not offer, or be properly qualified, a preference will be given to the surgeon's pupil of the hospital.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL,

Charing Cross.

Physician, _____, Surgeon, Mr. Guthrie. This hospital is open to students on Tuesdays and Thursdays at twelve o'clock. Terms of attendance, 5*l.* 5*s.* The lectures on the anatomy, diseases and operations of the eye, although forming a part of the lectures on surgery delivered by Mr. Guthrie every Monday and Friday evenings, are free to students attending the practice of the Ophthalmic Hospital.

LONDON INFIRMARY FOR CURING DISEASES OF THE EYE,

Moorfields.

Physician, Dr. Farre; Surgeons, Messrs. Tyrril and Scott. Three months, 5*l.* 5*s.*; six months, 8*l.* 8*s.*; perpetual, 10*l.* 10*s.* Days of operating, Thursdays at one o'clock.

PUBLIC DISPENSARY,

Bishop's Court, Chancery Lane.

Medical Practice.—Physicians, Dr. Burne, Mondays and Thursdays, at a quarter after twelve o'clock; Dr. Waterfield, Tuesdays and Fridays, at a quarter after twelve o'clock. For six months, 4*l.* 4*s.*; for fifteen months, 6*l.* 6*s.*; perpetual, 10*l.* 10*s.*

Observations will be made upon the cases as they present themselves, and Clinical Lectures will be delivered occasionally, so as to form a course of practical medicine in the twelve months.

Certificates qualify for the Apothecaries' Hall.

VETERINARY COLLEGE,

St. Pancras.

Anatomy, Physiology, and Pathology of the Horse; Mr. Coleman. A course of lectures on the anatomy, physiology, and pathology of the horse commences on Monday, the 13th of November, at eleven o'clock in the morning. Terms, 21*l.*

THE ROYAL INSTITUTION,

Albemarle-street.

Plan of an extended and practical course of lectures and demonstrations on Chemistry, delivered in the laboratory of the Royal Institution, by William Thomas Brande, F.R.S. London and Edinburgh, Professor of Chemistry in the Royal Institution, and of Chemistry and Materia Medica to the Apothecaries' Company; and M. Faraday, D.C.L., F.R.S., F.G.S., &c. &c., Fullerian Professor of Chemistry in the Royal Institution.

These lectures will commence on the first Tuesday in October, at nine in the morning, and are continued every Tuesday, Thursday, and Saturday. Two courses are given during the season; they begin in October and terminate in May. The subjects comprehended in the courses are treated of in the following order * :—

Division I.—Of the Powers and Properties of Matter and the general laws of Chemical changes. 1. Attraction, crystallisation, chemical affinity, laws of combination and decomposition. 2. Heat, its influence as a chemical agent in art and nature. 3. Electricity, its laws and connexion with chemical phenomena. 4. Radiant matter.

Division II.—Of Undecomposed Sub-

* Mr. Brande's *Manual of Chemistry*, intended as a text book to these lectures, and Mr. Faraday's *Chemical Manipulation*, are published by Mr. Murray, Albemarle-street. The *Tables of the Chemical Equivalents* used in these lectures are sold by Mr. Newman, 122, Regent-street, and by Messrs. Renshaw and Rush, 356, Strand.

stances, and their mutual combinations. 1. Substances that support combustion: oxygen, chlorine, iodine, fluorine, bromine. 2. Inflammable and acidifiable substances: hydrogen, nitrogen, sulphur, selenium, phosphorus, carbon, boron. 3. Metals, and their combinations with the various substances described in the early part of the course.

Division III.—Vegetable Chemistry. 1. Chemical physiology of vegetables. 2. Modes of analysis, ultimate and proximate elements. 3. Process of fermentation, and its products.

Division IV.—Chemistry of the Animal Kingdom. 1. General views connected with this department of the science. 2. Composition and properties of the solids and fluids of animals. 3. Products of disease. 4. Animal functions.

In the first division of each course, the principles and objects of chemical science, and the general laws of chemical changes, are explained, and the phenomena of attraction, and of light, heat, and electricity, developed, and illustrated by numerous experiments.

In the second division, the undecomposed bodies are examined, and the modes of procuring them in a true form, and of ascertaining their chemical characters, exhibited upon an extended scale. The lectures on the metals include a succinct account of mineralogy, and of the methods of analysing and assaying ores.

This part of the course will also contain a full examination of pharmaceutical chemistry; the chemical process of the *Pharmacopœiæ* will be particularly described, and compared with those adopted by the manufacturer.

The third and fourth divisions relate to organic substances. The chemical changes induced by vegetation are here inquired into; the principles of vegetables, the theory of fermentation, and the character of its products are then examined.

The chemical history of animals is the next object of inquiry. It is illustrated by an examination of their component parts, in health and disease; by an inquiry into the chemistry of animal functions, and into the application of chemical principles to the treatment of diseases.

The application of chemistry to the arts and manufactures, and to economical purposes, are discussed at some length in various parts of the courses; and the most important of them are experimentally exhibited. The various operations of analysis are also shown and explained.

The admission fee to each course is *four guineas*; or, by paying *eight guineas*, gentlemen are entitled to attend for an unlimited time. Gentlemen who are in actual attendance at the medical and anatomical schools in London, are admitted to attend two courses of the above lectures upon the payment of *six guineas*. Life and annual subscribers to the Royal Institution are admitted to the above lectures on payment of *two guineas* for each course; or, by paying *six guineas*, are entitled to attend for an unlimited time.

Further particulars may be had by applying to Mr. Brande, to Mr. Faraday, or to Mr. Fincher, at the Royal Institution, Albemarle-street.

GUY'S HOSPITAL.

Mr. Higgins will commence his course of lectures on natural philosophy on Thursday evening, October the 3rd, at six o'clock P.M., to be continued every succeeding Thursday at the same hour. Single course, *2l. 2s.*; perpetual, *3l. 3s.* Tickets and syllabus may be had at the hospital of Mr. Stocker.

ROYAL DISPENSARY FOR DISEASES OF THE EAR,

10, Dean Street, Soho.

Mr. Curtis, Aurist to his Majesty and their Royal Highnesses the Duke and Duchess of Gloucester, and Surgeon to this Institution, will commence his next course of lectures on the anatomy, physiology, and pathology of the ear, and on the medical treatment of the deaf and dumb, on Tuesday, October 1st.

For particulars apply to Mr. Curtis, at his house, No. 2, Soho-square.—The Royal Dispensary is open to pupils.

DENTAL SURGERY.

Mr. Pickering, Surgeon-Dentist (late assistant in Paris to M. Le Docteur Regnard, inventor of the Mineral Succedaneum, and lecturer on Dental Surgery), begs leave to inform the Profession that he intends delivering a course of lectures on *Dental Surgery*, especially adapted for practitioners and medical students.

This course will consist of eight demonstrative lectures, and will take place at Mr. Tuson's Theatre of Anatomy, Little Windmill-street, on the 14th of October, at eight o'clock in the evening, and will be continued every Monday at the same hour.

Mr. Pickering will describe, in succession, all the various disorders and operations which affect the teeth, and the pupils will be practised in the use of the necessary instruments. Admittance One Guinea.

N.B.—In addition to the above course of lectures, Mr. Pickering undertakes to teach the art of making and setting artificial teeth and palates, and the mechanical department of the profession in all its branches.

For further particulars apply to Mr. Pickering, 43, Berwick-street, Soho.

ROYAL COLLEGE OF SURGEONS IN LONDON.

REGULATIONS of the Council respecting the professional education of candidates for the diploma.

I. Candidates will be required to bring proof

1. Of being twenty-two years of age.

APOTHECARIES' COMPANY.

REGULATIONS TO BE OBSERVED BY STUDENTS INTENDING TO QUALIFY THEMSELVES TO PRACTISE AS APOTHECARIES, IN ENGLAND AND WALES.

EVERY candidate for a certificate to practise as an apothecary will be required to produce testimonials,

Of having served an apprenticeship* of not less than five years to an apothecary :

Of having attained the full age† of twenty-one years :

And of good moral conduct ‡.

Students whose attendance on lectures commenced on or after January, 1831, must, in addition to these testimonials, adduce proof of having devoted at least two years to an attendance on lectures and hospital practice; and of having attended the following courses of lectures §:—

Chemistry ; two courses, each course consisting of not less than forty-five lectures.

Materia Medica || and *Therapeutics* ; two courses, each course consisting of not less than forty-five lectures.

Anatomy and Physiology.—*Anatomical Demonstrations* ; two courses, of the same extent as required by the Royal College of Surgeons of London.

Principles and Practice of Medicine ¶ ; two courses, each course consisting of not less than forty-five lectures. To be attended subsequently to the termination of the first course of lectures on chemistry, materia medica, and anatomy and physiology.

Botany ** ; one course, consisting of not less

* No gentleman practising as an apothecary in England or Wales, can give his apprentice a legal title to be admitted to examination, unless he is himself legally qualified to practise as an apothecary, either by having been in practice prior to or on the 1st of August, 1815, or by having received a certificate of his qualification from the Court of Examiners.

† As evidence of age, a copy of the baptismal register will be required in every case where it can possibly be procured.

‡ A testimonial of moral character from the gentleman to whom the candidate has been an apprentice, will always be more satisfactory than from any other person.

§ The lectures required in each course respectively, must be given on separate days.

|| Or on three courses of lectures given by the professor of materia medica at this hall; (the candidates having been apprentices of members of the society), each course consisting of not less than thirty lectures.

¶ In those schools where the courses of lectures are of six months' duration, students may commence their attendance on the lectures on the principles and practice of medicine, after having attended for three months the lectures on chemistry, materia medica, and anatomy.

** Certificates of attendance on the lectures

2. Of having been engaged six years in the acquirement of professional knowledge.

3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons*.

4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or seasons, each course to comprise not less than sixty lectures.

5. Of having attended lectures on the practice of physic, on chemistry, and on midwifery during six months; and on botany and materia medica during three months.

6. Of having attended during twelve months the surgical practice of a recognised hospital in London, Edinburgh, Dublin, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital.

II. Members and licentiates in surgery of any legally constituted College of Surgeons in the United Kingdom, and graduates in surgery of any University requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proofs of being twenty-two years of age, and of having been occupied five years in the acquirement of professional knowledge.

N. B.—Certificates will not be recognised, from any hospital, unless the surgeons thereto, or a majority of them, be members of one of the legally constituted Colleges of Surgeons in the United Kingdom, nor from any school of anatomy, physiology, surgery, or midwifery, unless the respective teachers be members of some legally constituted College of Physicians or Surgeons in the United Kingdom.

Certificates will not be received on more than two branches of science from one and the same lecturer, but

Anatomy and physiology,

Demonstrations and dissections,

Materia medica and botany,

will be respectively considered as one branch of science.

In the certificates of attendance on hospital practice, and on lectures, the dates of commencement and termination are to be inserted in words at full length.

All the required certificates are to be delivered at the College ten days before the candidate can be admitted to examination.

By Order of the Council,

EDMUND BELFOUR, *Secretary*.

27th April, 1831.

* An anatomical season is understood to extend from October to April inclusive, and to comprise at least 140 lectures on anatomy and physiology, occupying not less than one hour each, given on separate days; and at least 100 demonstrations of the like duration, given in a similar manner; exclusive of dissections; of which distinct certificates are required.

than thirty lectures. To be attended between the 1st of April and 31st of October.

Midwifery and the Diseases of Women and Children; two courses.

Forensic Medicine; one course. To be attended during the second year.

Students are likewise earnestly recommended to avail themselves of instruction in morbid anatomy.

The candidate must also have attended for twelve months, at least, the physician's practice at an hospital containing not less than sixty beds, and where a course of clinical lectures is given; or for fifteen months at an hospital wherein clinical lectures are not given; or for fifteen months at a dispensary connected with some medical school recognised by the Court*. No part of this attendance can be entered upon until the termination of one entire year from the commencement of attendance on lectures, nor until one course of lectures, at least, on chemistry, materia medica, anatomy, and the practice of medicine, have been attended, in the order prescribed by the regulations.

Students whose attendance on lectures commenced prior to the 1st of February, 1828, will be admitted to examination in conformity with the regulations published in September, 1826, viz. after an attendance on,

One course of lectures on chemistry;

One course of lectures on materia medica;

Two courses of lectures on anatomy and physiology;

Two courses of lectures on the theory and practice of medicine;

And six months' physician's practice at an hospital, or nine months' at a dispensary.

Those who began to attend lectures subsequently to the 1st of February, 1828, and previously to the 1st of October of the same year, in conformity with the regulations of September, 1827, viz. after an attendance on

One course of lectures on chemistry;

One course of lectures on materia medica and botany;

Two courses of lectures on anatomy and physiology;

Two courses of lectures on the theory and practice of medicine; these last having been attended subsequently to the lectures on chemistry and materia medica, and to one course at least of anatomy;

And six months', at least, physician's practice at an hospital, or nine months' at a dis-

pensary; such attendance having commenced subsequently to the termination of the first course of lectures on the principles and practice of medicine.

Those whose attendance on lectures commenced in October, 1828, must have complied with the regulations of September, 1828, viz. by having attended

Two courses of lectures on chemistry;

Two courses of lectures on materia medica and botany;

Two courses of lectures on anatomy and physiology;

Two courses of anatomical demonstrations;

Two courses of lectures on the theory and practice of medicine; these last having been attended subsequently to one course of lectures on chemistry, materia medica, and anatomy.

And six months', at least, the physician's practice at an hospital, containing not less than sixty beds, or nine months' at a dispensary; such attendance to have commenced subsequently to the termination of the first course of lectures on the principles and practice of medicine.

All students who began to attend lectures in January, 1829, are required to have attended the physician's practice at an hospital for nine months, or at a dispensary for nine months, and to have attended

Two courses of lectures on midwifery, and the diseases of women and children.

The testimonials of attendance on lectures, and hospital practice, must be given on a printed form, with which students may be supplied, on application at the under-mentioned places:—

In London, at the beadle's office, at this Hall; in Edinburgh, at Messrs. MacLachlan and Stewart's, booksellers; in Dublin, at Messrs. Hodges and Smith's, booksellers.

In the provincial towns, where there are medical schools, from the gentlemen who keep the register of the school.

No other form of testimonial will be received; and no attendance on lectures will qualify a candidate for examination, unless the lecturer is recognised by the Court.

The names of the lecturers recognised by the Court may be seen on application to the several gentlemen acting as registrars in the provincial schools, and at the beadle's office at the Hall.

The teachers in London, Dublin, Edinburgh, Glasgow, and Aberdeen, recognised by the constituted medical authorities in those places respectively, are recognised by the Court; and certificates given by the medical professors in the continental universities are also recognised and received by the court.

RECOGNITION OF LECTURERS.

Gentlemen wishing to be recognised as lecturers are referred to the following resolutions of the Court, passed on the 18th of Nov. 1830, viz. :—

Resolved—That no member of the Court of

and demonstrations given at the society's garden, and also at the herbarisings for two entire seasons will be received as equivalent, from such candidates as have been apprentices of members of the society.

* The Court are willing to recognise dispensaries upon receiving a satisfactory assurance from the physicians of those institutions, that adequate arrangements exist for affording instruction to students in practical medicine.

Examiners shall be recognised as a lecturer on any branch of medical science.

That the Court will not recognise any *new* teacher who may give lectures on more than *two* branches of medical science; nor will they sanction a teacher already recognised in giving lectures on any new branch of the science, if already he gives lectures on *two*.

That the Court will not recognise a teacher until he has given a public course of lectures on the subject he purposes to teach; but if, after such preliminary course of lectures the teacher should be recognised, the student's certificate of attendance on that course will be received.

That the Court will not recognise a teacher until he has produced very satisfactory testimonials of his attainments in the science he purposes to teach, and also of his ability as a teacher of it, from persons of acknowledged talents and of distinguished acquirements in the particular branch of science in question.

That satisfactory assurance shall also be given that the teacher is in possession of the means requisite for the full illustration of his lectures, viz., that he has, if lecturing on *Chemistry*, a laboratory and competent apparatus; on *Materia Medica*, a museum sufficiently extensive; on *Anatomy and Physiology*, a museum sufficiently well furnished with preparations, and the means of procuring recent subjects for demonstration; on *Botany*, a hortus siccus, plates or drawings, and the means of procuring fresh specimens; on *Midwifery*, a museum, and such an appointment in a public midwifery institution, as may enable him to give his pupils practical instruction.

That the lecturer on the principles and practice of medicine must be, if he lectures in London, or within seven miles thereof, a fellow, candidate, or licentiate of the Royal College of Physicians of London; and if he lectures beyond seven miles from London; and should not be thus qualified, he must be a graduated doctor of medicine of a British University of four years' standing (unless previously to his graduation he had been for four years a licentiate of this Court).

That the lecturer on materia medica and therapeutics must be a fellow, candidate, or licentiate of the Royal College of Physicians of London; a graduated doctor of medicine of a British University of four years' standing (unless previously to his graduation he had been for the same length of time a licentiate of this Court), or he must be a licentiate of this Court of four years' standing.

That the lecturer on anatomy and physiology must either be recognised by the Royal College of Surgeons of London, or must be a member of that College of four years' standing.

That the demonstrator of anatomy must either be recognised by the Royal College of Surgeons of London, or must be a member of that College.

DISPENSARIES AS SCHOOLS OF PRACTICAL MEDICINE.

The Court will recognise, as schools of practical medicine, such dispensaries as shall give satisfactory evidence on the following points, viz.—

That the dispensary is situated in some city or town in which there is a medical school recognised by the Court.

That the rules for the government of the dispensary permit the attendance of students, and that the physicians afford them instruction, and opportunities of acquiring practical knowledge in medicine.

That the dispensary (if within the limits of the jurisdiction of the Royal College of Physicians of London) is under the medical care of at least two physicians, each of whom is a fellow, candidate, or licentiate of the Royal College; and if beyond these limits, that it is under the care of at least two physicians, who, if not so qualified, are graduated doctors of medicine of a British university, of four years' standing.

And that the apothecary of the dispensary is legally qualified, either by having been in practice prior to or on the 1st of August, 1815, or by having received a certificate of qualification from the Court of Examiners.

REGISTRATION.

A book is kept at the Hall of the Society for the registration, at stated times, of the names of students, and of the lectures, hospitals, or dispensaries they attend.

All students, in London, are required to appear personally, and to register the several classes for which they have taken tickets; and those only will be considered to have complied with the regulations of the Court whose names and classes in the register correspond with the testimonials of the teachers.

The book will be open for the registration during the first twenty-one days of the months of October, February, and June, from nine o'clock until two.

The Court also require students at the provincial medical schools to register their names in their own hand-writing, and the classes they attend, with the registrar of each respective school, within fourteen days from the commencement of each course of lectures, and those students only will be deemed to have complied with the regulations whose names are so registered.

The registrar of each respective school is requested, as soon as may be convenient after the termination of each scholastic year, to send to the secretary of the Court a list of the names of the students registered with him during that year.

Names of gentlemen having the care of the Registers.

Bath—R. T. Gower, Esq. and John Spender, Esq., Lecturers on Anatomy.

Birmingham—W. Sands Cox, Esq., ditto.
Bristol—Dr. Wallis and Henry Clark, Esq. ditto.

Hull—Edward Wallis, Esq. and Robert Craven, Esq.; ditto.

Leeds—Thomas Poigden Teale, Esq., ditto.

Liverpool—William Gill, Esq., ditto.

Manchester—Joseph Jordan, Esq. Thomas Turner, Esq. and Thomas Fawdington, Esq., ditto.

Sheffield—Wilson Overend, Esq. and W. Jackson, Esq., ditto.

Each student at his first registration will receive the printed form on which he is to obtain the certificate of his teachers.

EXAMINATION.

Every person offering himself for examination must give notice in writing to the Clerk of the Society on or before the Monday previously to the day of examination, and must also at the same time deposit all the required testimonials at the office of the Beadle, where attendance is given every day, except Sunday, from 9 till 2 o'clock.

Candidates will be admitted to examination in the order in which their names stand on the Notice-paper; and those neglecting to attend agreeably to their notice, will, upon a subsequent application, be placed at the bottom of the list.

The examination of the candidate for a certificate of qualification to practise as an apothecary, will be as follows:—

1. In translating parts of Celsus de Medicina, or Gregory's *Conspectus Medicinæ Theoreticæ*, Physicians' Prescriptions, and the *Pharmacopœia Londinensis*.

2. In Chemistry.

3. In *Materia Medica* and Therapeutics.

4. In Botany.

5. In Anatomy and Physiology.

6. In the Principles and Practice of Medicine*.

The examination of a candidate for a certificate of qualification to act as an assistant to an apothecary, in compounding and dispensing medicines, will be as follows:—

1. In translating physicians' prescriptions, and parts of the *Pharmacopœia Londinensis*.

2. In Pharmacy and *Materia Medica*.

By the 22nd section of the Act of Parliament, no rejected candidate for a certificate to practise as an apothecary can be re-admitted to be examined until the expiration of six months from his former examination; and no rejected candidate as an assistant until the expiration of three months.

The Court meet in the Hall every Thursday, where candidates are required to attend at a quarter before four o'clock.

The Act directs the following sums to be paid for certificates:—

For London, and within ten miles thereof, ten guineas.

For all other parts of England and Wales, six guineas.

Persons having paid the latter sum become entitled to practise in London, and within ten miles thereof, by paying four guineas in addition.

For an assistant's certificate, two guineas.

By order of the Court,

JOHN WATSON, Secretary.

Apothecaries' Hall,
September, 1833.

For information relative to these regulations medical students are referred to Mr. Watson, who may be seen at his residence, 43, *Berners-street*, between the hours of nine and ten o'clock every morning (Sunday excepted); and for information on all other subjects connected with the "Act for better regulating the Practice of Apothecaries," application is to be made to Mr. Edmund Bacot, clerk of the society, who attends at the Hall every Tuesday and Thursday, from one to three o'clock.

It is expressly ordered by the Court of Examiners, that no gratuity be received by any officer of the Court.

PHYSIOLOGICAL NOTES.

Life.—The word life, as commonly used, does not denote an individual fact, or a simple idea, and cannot therefore be *defined*. It is applied to a certain assemblage and succession of phenomena which are seen in a great variety of the objects that surround us, and distinguish them from the other objects of our senses. When these phenomena are examined throughout the whole of nature, it is found that the most general and characteristic of them is the continued appropriation and assimilation of surrounding matter which we call *nutrition*, a process which maintains a certain definite structure called *organisation*, which originates in all cases that can be satisfactorily observed, by *generation*, and terminates by *death*.

Some have conjectured that the phenomena of life, as they are seen only in bodies more or less organised, depend merely on the circumstance of *organisation*, but when we inquire how organisation has been effected, we

* This branch of the examination embraces an inquiry into the diseases of pregnant and puerperal women, and also into the diseases of children.

find that it implies in every instance where we can observe it, the previous existence of vitality, and therefore must be regarded as one of its effects, not as its cause.

Others have formed the supposition of a *material substance*, such as an ethereal or subtile fluid, superadded to organisation during life, and producing the phenomena of life, but this idea is both unsupported by evidence, and useless in the explanation of facts.

Vital Contraction.—When this contraction takes place, the filaments constituting the muscular fibres assume a zig-zag form, the angles formed being always at the same points, and being generally obtuse, but in the case of any forcible contraction, acute; the fibres become rigid and elastic, and it would appear, swell out towards their centres, but experiments show that their real bulk is not altered, the change being in the relative position, not in the size or distance of their ultimate particles.—*Dr. Alison's Physiology and Pathology.*

THE
London Medical & Surgical Journal
Saturday, September 28, 1833.

ADDRESS TO OUR READERS.—OUR
FUTURE ARRANGEMENTS.

AT the commencement of another medical session, we owe it to our readers to inform them of the advantages we shall offer them in the ensuing volume of this periodical. We are happy to state that we have completed such arrangements as will enable us far to exceed our contemporaries. We shall publish regularly the following lectures,—Professor Cooper's on Surgery, delivered at the University; Professor Mayo's of King's College, on clinical surgery, at the Middlesex hospital; Professor Guthrie's on the

diseases of the urinary organs, at the Westminster hospital; those on clinical surgery by Dr. Crampton, Surgeon-general to the forces in Ireland, delivered at the Meath hospital, or county of Dublin infirmary; Baron Dupuytren's clinical lectures at the Hotel Dieu, and Baron Alibert's on the skin, at the hôpital St. Louis, Paris. We hope to complete arrangements for an Edinburgh course. We shall publish three lectures weekly, and shall thus place before our readers the opinions of many of the most eminent physicians and surgeons of the present day. We have the consent of every individual whose lectures we insert, and we are not so unprincipled as to publish the lectures of any one contrary to his wishes. We are not compelled to fill our pages with lectures delivered two or three years ago, or with such crudities as characterise some of our contemporaries. Few are aware of the expense incurred in reporting so many courses of lectures, but we are determined that the LONDON MEDICAL AND SURGICAL JOURNAL shall be worthy of its name, and shall surpass in character and contents all rival publications. The second part of this journal will be occupied by reviews, original communications, British and foreign hospital reports, accounts of the progress of the medical sciences in different countries, reports of the proceedings of the scientific and medical societies in this metropolis, with a variety of miscellaneous matter.

The quantity of scientific and practical knowledge accumulated in this

periodical, and rendered accessible to every one engaged in the study and practice of medicine, by the great moderation in price, should, we think, place it in the possession of all who undertake the responsibility of treating disease and preserving human life. The student and the practitioner are presented in this Journal with the best elementary and practical lectures, they are made acquainted with the merits and defects of the latest works, by fair and impartial reviews, they have clinical reports of the most interesting cases occurring in our own and foreign hospitals, forming together an epitome of the advancement of the medical sciences in all countries, with a variety of miscellaneous scientific information at the lowest possible expense *. Economy is now practised by all men, and on this ground alone, independently of the higher consideration of information and knowledge, this work could not have failed to be universally encouraged. We have great pleasure in making this acknowledgment, and take this opportunity of assuring our subscribers, that every effort will be made by us to maintain their good opinion. We shall continue to supply them with the latest intelligence on the progress of science, and thus enable our friends to become acquainted with information which their predecessors, now busily engaged in practice, can never acquire. We fully assent to the opinion of Sir Astley Cooper, that

“students now a-days are better informed than teachers were forty years ago.” Those now commencing the study of medicine generally avail themselves of the opportunities of acquiring knowledge, afforded by the medical press; while their seniors, with few exceptions, neglect such advantages, and plod their weary and benighted way with scarcely a ray of science to guide them. Those of the old school are, in general, in this position, and however extensively they may be engaged in practice, are infinitely inferior in point of knowledge to the present candidates for diplomas. At no period of the history of medicine, was there so great a love for literature and science as at present, the diffusion of knowledge is, in these countries, universal. Every student, on obtaining his degree, or diploma, subscribes to one or more periodicals, to keep pace with the rapid progress of improvement in his favourite pursuit, and hence he speedily leaves his old established rival immeasurably behind him. Knowledge indeed is power, and ignorance weakness. Daily observation tests this position. It is well known that young medical practitioners soon triumph over an old opponent, however respected or popular.

COURT-MARTIAL.

GENERAL ORDERS BY HIS EXCELLENCY THE
COMMANDER-IN-CHIEF.

*Head-Quarters, Choultry Plain, 16th
March, 1833.*

THE following extract from the confirmed proceedings of an European general court-martial, holden at Canamore, on Wednesday, the sixth day

* This Journal consists of two volumes annually, containing an equal quantity of matter with rival publications, and of a much better description, at one-third less price.

of March, one thousand eight hundred and thirty-three, by virtue of a warrant from his Excellency Lieutenant-general the Hon. Sir Robert William O'Callaghan, K.C.B., Commander-in-Chief, are published to the army.

John Barnes, senior assistant-apothecary, attached to the garrison hospital of Cannamore, placed in confinement by my order, on the following charges:—

First Charge.—For having, at Cannamore, on the twenty-fifth of October, one thousand eight hundred and thirty-two, embezzled, or fraudulently misapplied, the under-mentioned articles, being stores belonging to the East India Company, intrusted to his care; namely, two ounces and four drachms of solution of acetate of lead, two ounces of oil of croton, three ounces and four drachms of oil of turpentine, three ounces and four drachms of olive oil, five ounces and four drachms of aromatic spirit of ammonia, two ounces of tincture of benzoin, six ounces of tincture of cardamom, one ounce of cantharides, four ounces and four drachms of tincture of myrrh, eight ounces of tincture of opium, ten grains of acetate of morphine, six ounces of isinglass, six drachms and forty grains of powder of squill, one bolus knife, four bleeding lancets, one abscess lancet, two pewter syringes, two pewter funnels, one pewter ounce measure, one package of ligature thread, two glass stoppered bottles, thirteen phials.

Second Charge.—For conduct to the prejudice of good order and military discipline, in having, at the same time and place, had in his possession the undermentioned articles, belonging to the East India Company, without being able satisfactorily to account how he came by the same: namely—two ounces of sulphuric aether, six ounces and four drachms of spirits of wine, eight ounces of acetic acid, four ounces and four drachms of nitric acid, six ounces and four drachms of sulphuric acid, four ounces of balsam of

copaiba, one ounce and five drachms of balsam of Peru, one ounce and four drachms of soap liniment with opium, two ounces and four drachms of solution of acetate of lead, three ounces of oil of croton, one ounce and three drachms of oil of aniseed, two drachms and thirty grains of oil of peppermint, five drachms of oil of cinnamon, four pounds and eight ounces of castor oil, three ounces and four drachms of oil of turpentine, three ounces and four drachms of oil of olive, five ounces and four drachms of aromatic spirits of ammonia, fourteen ounces of foetid spirits of ammonia, one ounce and three drachms of spirits of lavender, two ounces of tincture of benzoin, six ounces of tincture of cardamom, four ounces of tincture of castor, three ounces of tincture of foxglove, two pounds and eight ounces of tincture of kino, one ounce of tincture of cantharides, four ounces and four drachms of tincture of myrrh, two pounds of tincture of opium, four ounces of compound tincture of camphor, four pounds of wine of aloes, one pound and eight ounces of wine of iron, fifteen ounces one drachm and thirty grains of Burgundy pitch, four ounces and three drachms of gum Arabic, ten grains of acetate of morphine, one ounce two drachms and thirty grains of acetate of lead, one ounce of acetate of potass, one ounce six drachms and twenty grains of aloes, six ounces and forty-four grains of tartarised antimony, six drachms of assafoetida, one ounce and six drachms of calumba powder, two ounces and seven drachms of prepared chalk, two ounces and twenty grains of camphor, two ounces six drachms and forty grains of Cheltenham salts, one pound three ounces and four drachms of plaster of galban, ten ounces of lead plaster, one pound and five ounces of plaster of quicksilver, eleven ounces of plaster of resin, six ounces of soap plaster, one drachm of gamboge, one ounce and twenty grains of liquorice root, three drachms and thirty grains of nitric oxide of quicksilver, three ounces six drachms and thirty grains of oxy muriate of quick-

silver, five drachms and twenty grains of white prepared quicksilver, nine ounces of jalap, six ounces of isinglass, six ounces of ipecacuanha, two pounds and nine ounces of Epsom salts, two ounces and two drachms of manna, thirty grains of mastic, four ounces and twenty grains of opium, eleven ounces of cream of tartar, three ounces and three drachms of antimonial powder, one ounce six drachms and twenty grains of aromatic powder, eight drachms and fifty grains of James's powder, six drachms of Dover's powder, nine ounces and four drachms of quassia, one ounce and two grains of quinine, two ounces two drachms and thirty grains of rhubarb, thirty grains of saline powder, four drachms of scammony, six drachms and forty grains of squill powder, eight ounces of senna leaves, two ounces of simarouba, one bolus knife, two small scale boxes, seventeen bougies, one bougie case, six bleeding lancets, one gum lancet, one abscess lancet, one seton needle, two pewter syringes, one ivory syringe, two pewter funnels, one pewter ounce measure, one ounce glass measure, three ounces of ligature thread, eleven phial corks, one ivory clyster pipe, two glass stoppered bottles, thirteen phials, four quires of foolscap paper, four quires of country foolscap paper, six sheets of blotting paper, one package of ink-powder, one piece of India-rubber, four cotton thread lamp wicks, one ounce and two drachms of sponge, one marble mortar, two marble tipped pestles, ten ounces of fine tow.

The above being in breach of the articles of War.

(Signed) J. HASLEWOOD, *Garrison Surgeon.*

Cannamora, 4th January, 1833.

By order:

(Signed) B. R. HITCHINS, *Actg. Gen. of the Army.*

The court having most maturely weighed and considered the whole of the evidence brought forward in support of the prosecution, as well as

what the prisoner, John Barnes, senior assistant-apothecary, attached to the garrison hospital of Cannamora, has urged in his defence, and the evidence in support thereof, is of opinion,

Finding on the First Charge— That the prisoner is guilty of the first charge, with the exception of the four bleeding lancets; the court find that there were only two.

Finding on the Second Charge— That the prisoner is guilty of the second charge.

Sentence.—The court having found the prisoner guilty as above stated, doth sentence him, the said John Barnes, senior assistant apothecary, attached to the garrison hospital of Cannamora, to be dismissed from the service of the Honourable East India Company, and further, that he be rendered incapable of serving the Company in any office, civil or military.

(Signed) A. WOODBURN, *Capt., Dep. Judge Advocate-General.*

Confirmed.—In confirming this sentence, in order that the service may be relieved from a person who has been guilty of so gross an act of dishonesty, I consider it necessary to record an opinion that the punishment awarded is altogether incommensurate with the nature and degree of the offence of which the prisoner has been convicted. If the subordinates of the medical department are to be deterred from embezzling the stores which are necessarily intrusted to them, through the fear of dismissal only, there can be but little security for public property of that description; as the value of the drugs stolen may frequently exceed the value of the situation lost, which is evidently the case in the present instance.

(Signed) R. W. O'CALLAGHAN, *Lieut.-Gen. and Com.-in-Chief.*
Madras, 16th of March, 1833.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Rupture of the left kidney.—A man of strong and healthy constitution, ætat. 40, was admitted into the hospital some weeks ago, having received a violent blow in the loins, which caused hæmorrhage from the urethra. It was supposed that the left kidney was ruptured, a diagnosis which was strengthened by the profuse bleeding from the urinary canal, and by the acute sensation of pain and uneasiness felt by the patient in the region of the kidney. Some weeks after his admission an abscess formed upon his back, midway between the last rib and the crista ili, which Mr. Stanley believed to communicate with the intestine. The patient expelled large quantities of wind through the external opening of the abscess, from which he expressed great relief. He has been taking three grains of hyoscyamus thrice a day, and is now put on moderate doses of blue pill. He is at present convalescent, has regular evacuations by stool, and sleeps well at night.

Successful employment of tourniquets in a disunited fracture of the femur of twenty-one weeks' standing, and which resisted all the ordinary means of procuring union of the fractured extremities of the bone.—In a case of disunited fracture of the femur of long standing (reported in a former number of the journal) where all the usual means of promoting union failed, notwithstanding the excellent health of the patient, who is a middle aged man, tourniquets were tightly applied round the fractured part of the limb. This treatment has been completely successful, as the patient now feels a sense of strength and security in the limb, which he did not before experience, and feels confident of being able to stand and walk on his legs. It is now upwards of twenty-one weeks since the fracture occurred. The

tardy progress of union in this case is surprising, when the good health and age of the patient are considered.

OBITUARY.

DEATH OF DR. JOHN GORDON SMITH.

It is with feelings of considerable regret that we record the death of Dr. Gordon Smith, which took place on the 16th inst., in the forty-first year of his age.

The biography of Dr. Smith abounds with many instructive topics. After the best education, and having attained the highest honour in medicine at Edinburgh, he entered the army, and was greatly esteemed by his brother officers for his gentlemanly demeanour and his humanity to the sick. He was well versed in the ancient and modern languages, and was enthusiastically devoted to literature and science. During his military career he witnessed the greatest victories. He was attached to the 12th Lancers at Waterloo, and received the highest eulogium from Colonel Ponsonby, whose life he saved, and for his indefatigable attention to the sick and wounded.

Soon after the peace of 1815, he retired on half pay, and fixed his residence in London. He was a cheerful, witty, and pleasant companion, and his society was much solicited. He soon discovered that it was a difficult matter to succeed in practice in London; as he did not belong to the College of Physicians; and had no chance as an operative or consulting surgeon, as he was not attached to a metropolitan hospital. Under these circumstances he accepted the office of physician to the Duke of Sutherland (late Marquess of Stafford), with whom he resided for four years. During this period he occupied his leisure hours in composing his work on Forensic Medicine. This was a hazardous undertaking at the time, as medical jurisprudence was not then included in the courses of study required by the Universities or Colleges. It was taught, however, at the Edinburgh University by the late Professor Duncan; but, as it was optional with students to attend it, very few availed themselves of the opportunity. There was no work on the subject in our language except Dr. Farre's Translation of Mahon's Manual, and Dr. Male's Elements, both mere outlines. Dr. Smith's Forensic Medicine was most favourably received by the medical and legal professions, who considered it a work of reference and authority. The style was elegant and classic; but the author was perhaps too diffuse on the immorality of crime, while he was not sufficiently minute in what related to medicine. Soon after the appearance of this publication Dr. Smith commenced lectures on

Medical Jurisprudence, which were repeatedly delivered at the Royal Institution of Great Britain and at the Mechanics' Institution, and excited much interest. On the establishment of the Medical School at the London University, Dr. Smith was elected Professor of Medical Jurisprudence. His was, however, a nominal chair, as neither the Courts of Examiners of the Royal College of Surgeons nor of the Apothecaries' Society enforced the study of this important branch of medical education. Dr. Smith was therefore lecturing to few pupils, and was much dispirited at the neglect of his favourite subject.

He remained without a class for two years, and then requested the editor of this Journal, who was the only other lecturer on medical ethics and jurisprudence in London at the time, to join him in a memorial to the Company of Apothecaries. A memorial was presented, but produced no immediate effect; Dr. Smith felt annoyed, and a few days before the apothecaries recognised forensic medicine as a branch of medical education, he resigned his professorship in the University. His friends in the Council of the University now endeavoured to reinstate him, but they failed. Here it is but justice to the managers of the Institution to state, that there was something in the conduct of their late professor which was contrary to one of their resolutions. They had resolved that none of their medical professors should enter into the ephemeral discussions on medical politics, which were of frequent occurrence in periodicals, but the subject of this notice acted contrary to this rule. The University being shut against him, all his hopes were blighted, his only resource was that of a private lecturer, but as the apothecaries required the study of jurisprudence only during the last year of attendance, and not of those who had already commenced their studies, scarcely a single pupil entered to the lectures on the subject. Dr. Smith felt indignant that he, who had virtually established it as a science in his native country, was deprived of every advantage that might accrue from it, he became irritable and misanthropic, and thought the public and the profession had used him cruelly. About this period the city coroner died, and he offered himself for the situation: here also he failed. He then found that all his hopes had vanished, his mind became dejected, his habits intemperate, and he was finally consigned to prison. Here he remained for fifteen months, when death put an end to his sufferings. During his confinement, he was deserted by all his acquaintances, with two exceptions, Dr. Harrison and ourselves. Dr. H., much to his credit, was a frequent visitor, and, like the good Samaritan, poured oil and wine upon the wounds of his friend,

and contributed the most substantial aid for his relief and comfort.

Thus ended the career of a physician who had done much for science and for humanity. By his exertions medical practitioners were compelled to study a science of the utmost importance to themselves, and of the greatest consequence to the character, property, and lives of every class in society. The discrepancy of medical evidence had long been a source of merriment and sarcasm in courts of justice, and of contempt and ridicule with the public. It can be so no longer, at least among the rising race of practitioners; and reputation, liberty, and life, will not henceforth be sacrificed by medical witnesses. The legal profession now study medical jurisprudence; and woe betide the medical witness who is ignorant of the subject. Dr. Gordon Smith, with all his misfortunes, effected this beneficial improvement in judicial investigations. His works on Forensic Medicine, Medical Evidence, and on the Examination of Medical Witnesses, will be referred to, though they are far behind the present state of science. His Sketches of Waterloo have been most favourably received by the public. He wrote various Essays both in the medical and other periodicals, and was formerly Editor of the London Medical Repository. He was a humane and learned physician, a moral and valuable member of society, and a gentleman highly esteemed by his profession.

BOOKS.

Signs of Pregnancy and Delivery. By W. F. MONTGOMERY, M.D. (From the Cyclopædia of Practical Medicine.) Royal 8vo. pp. 45. London.

An essay evincing profound research, great discrimination, judicious arrangement, and much talent.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,
BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LVII., DELIVERED FEB. 22, 1833.

GENTLEMEN,—I explained to you, yesterday evening, that the surgical cure of aneurism was accomplished on two principles;—the first being that of simply lessening the flow of blood into the sac—of diminishing its impetus; the second, that of cutting off entirely the main current of blood to it. I also mentioned, that unless you could completely fulfil the second principle, the prospect of a cure would be very uncertain. In fact, it is known by experience, that few aneurisms can be successfully treated, either surgically or medically, except on this principle. I likewise informed you, that after you had secured the main artery leading into the sac, such blood as is in the aneurismal cavity will gradually acquire a solid form. Generally, for some time after the operation, a slight current of blood continues to find its way into the sac; but, by degrees, the quantity diminishes, and the retardation of the blood's motion always promotes the coagulation and consolidation of it. Afterwards, the whole tumour gradually diminishes, and is finally absorbed. Not only does the sac become filled with solid lamellated blood, but also a portion of the artery, both above and below it, is obliterated in the same manner, and this as far in each direction as the origin of the first large collateral branch. Here, gentlemen, is a specimen of a popliteal aneurism, taken from a patient who died three months after the operation; the tumour, you will observe, is diminished one-third: you see, that the artery is obliterated where it is tied, and a portion of the vessel, above and below the tumour, is filled with the same coagulum as is found in the aneurismal cavity itself.

VOL. IV.

Formerly it was the custom, in operating for the cure of aneurism, to lay the sac open and take out the coagulum, and then, after having sought for the communication between the aneurism and the artery, to tie the artery close to such communication; but this was of course a very severe operation, and frequently led to dangerous consequences, always to extensive suppuration, and often to fatal secondary hæmorrhage; for the artery was not tied according to the principles which science and experience now sanction, and a diseased portion of it was actually selected for the ligature—a most objectionable proceeding. At the present day, surgeons take care to secure the artery at a convenient distance from the aneurism, and in a situation where it is most likely to be sound; they do not open the aneurism and take out the coagulum, but leave the whole tumour undisturbed, and to be quietly removed by the absorbents. The aneurismal swelling, in the preparation before us, has been reduced not less than one-third by absorption in the course of three months.

Now, gentlemen, after what has been stated, you will understand, that, in order to perform the operation, so as to give the patient the best chances of recovery, it is necessary to attend to certain principles, without which, or what is the same thing, without the benefit of a skilful, well-informed operator, who would duly attend to them, the prognosis must always be unfavourable. The first principle is, always to make a sufficiently free division of the skin. Some practitioners suppose they can save the patient pain by making a small opening, but this is a mistake; and you will find, that in the generality of bad operations for aneurism, the external opening has not been made extensive enough. The diminutive size of the opening in the skin embarrasses the surgeon in all the future stages of the operation, which is rendered tedious, more painful, and less likely to succeed, than if a proper first incision had been made. The second principle is, to observe not to include in the ligature any large nerve or vein which may happen to be near the artery. The third principle, and a most important one, is to disturb the artery as little as possible, and not to detach it more than is

U

necessary from its surrounding connections. You should not, therefore, adopt the plan of trying to get your finger under the artery, for you could not do this without detaching the vessel from its surrounding connections further than would be proper. I explained, in the lectures on hæmorrhage, that if the ligature be applied to a part of an artery, which does not receive its proper supply of nourishment through the vasa vasorum, it will be very likely to ulcerate and slough; therefore you should not detach the artery any further than you can help from its natural connections, and, by attending to this rule, you will leave it in that desirable and advantageous condition in which it continues to receive its usual supply of blood. Then, gentlemen, I recommend you always to avoid including the sheath of the artery in the ligature: let the vessel be completely exposed by opening the sheath, and let it next be tied by passing the ligature under it with an aneurismal needle or an eye-probe. The aneurismal needle ought not to be so sharp or pointed as to create any risk of the vessel being wounded by it, nor yet so blunt as to require much force to make it pass through the cellular substance connecting the artery to its sheath. Another principle is, not to let the ligature be of a large, thick, clumsy make, and irregular shape; on the contrary, it should be evenly round, and not larger than is required for the proper degree of strength. Dr. Veitch, a naval surgeon, assures me that he was the first operator who actually tied the arteries with single threads, which was unquestionably a grand improvement. The smaller a ligature is, with due attention to the latter quality, the better, and therefore many surgeons prefer, as the material for ligatures, dentists' silk, which has great strength in proportion to its diameter. You apply the ligature so as purposely to divide the internal and fibrous coats of the artery, and adopt such measures as will give the wound the best chance of healing by the first intention. Formerly, large ligatures were used, through an apprehension that fine ones might cut completely through the artery; but it is now known that this was a false alarm. A thick ligature has several disadvantages; for, in the first place, it is necessary, for its application, to expose more of the vessel than is advisable, and, in the second, it forms a larger quantity of extraneous matter in the wound than ought to be there. It is on these principles that the thick clumsy construction of the ligature often has the chief share in causing operations for an aneurism to prove fatal by secondary hæmorrhage. Sometimes, when such a ligature is employed, it is likewise apt to become suddenly loose, almost before the patient returns to his bed; and the reason of this occurrence depends upon the difficulty of applying a large clumsy ligature in a regular close circle round the artery. It was in vain that surgeons tried to prevent the disaster, by applying two ligatures, dividing the artery

between them, and then transfixing the mouth of the vessel with the ends of the ligatures, whereby it was conceived the noose would be mechanically kept from slipping. Gentlemen, we now know that the hæmorrhage arose from the insecure hold which the wrong kind of ligature had of the artery; and the knowledge of this fact makes us see at once the remedy for the inconvenience, namely, the selection of a different sort of ligature, and the application of it according to the principles dictated by the experience of the best modern surgeons. The comprehension of these principles enables us to judge correctly of the little merit pertaining to some other contrivances for the prevention of bleeding from an artery, tied for the cure of an aneurism, especially to what are termed *ligatures*. After tying the artery in two places, and dividing it between the ligatures, another loose ligature (the ligature of reserve) was left round the artery above the ligature nearest the centre of the circulation, ready to be tightened immediately hæmorrhage commenced. But such a ligature has quite a contrary effect to what was intended, for it renders secondary hæmorrhage more certain of taking place, for reasons you must be already aware of; in fact, its application makes it necessary to detach a considerable portion of the artery from its surrounding connections, and likewise increases the quantity of cutaneous matter in the wound, while the ligature, tightened in the first instance, is really on a portion of the artery so detached as almost to be sure of ulcerating or sloughing. Ligatures of reserve, therefore, long relinquished in England as dangerous expedients, are now beginning to be rejected in every part of the world where surgery is in a high state of cultivation.

With respect to the plan of applying two ligatures and dividing the artery between them, this was originally proposed by the late Mr. Abernethy, about five-and-twenty or thirty years ago, before which period secondary hæmorrhage was very common, because the proper principles to be observed in the application of ligatures were then not understood: large ligatures were used, and other things done, which were disadvantageous to the patient's chance of recovery. With a view of lessening the frequency of secondary hæmorrhage, Mr. Abernethy considered it might be advisable to apply two ligatures, and divide the artery in the interspace between them. He was led to this idea, in consequence of his having noticed, that arteries on the face of a stump were more rarely affected with secondary hæmorrhage than after they had been tied for aneurism; and he conceived, that by putting the artery to be tied as nearly as possible in the same state as it was on the surface of a stump, it would be as little liable to secondary hæmorrhage. There can, I think, be no doubt that when an extensive portion of an artery has been laid bare, and separated from its natural connexions, it is indeed better to apply

two ligatures, one at each extremity of the detached part of the vessel, than to apply one at the middle of such portion, where the vessel must be cut off from its supply of nutriment. But, gentlemen, when we have the choice, a single ligature is preferable, that is to say, when we can employ it with direct attention to the principles which I have explained, of not disturbing the artery more than is absolutely necessary, and of not separating it from its natural connections, through which the *vasa vasorum* receive and return their blood. You should merely divide the sheath, and pass round the artery a strong but slender round ligature by means of a well-made aneurismal needle, such as I have described.

Now, with regard to the operation for aneurism, I need say nothing further till I come to the operations on the dead subject. I may, however, just mention one thing, which it is of great consequence to attend to, namely, the necessity of endeavouring to unite the wound as speedily as possible after the operation, in order to give the patient the best chance of recovery. I may also here advise you always to lessen the quantity of extraneous substance in the wound as far as you can, a rule that will lead you to cut off one of the ends of the ligature, before you bring the sides of the incision together. Some surgeons have done more than this, for they have cut off both ends of the ligature, leaving nothing but the circle of the noose; but this practice is now, I believe, abandoned, in consequence of troublesome abscesses having sometimes followed its adoption. One end of the ligature, I scarcely need say, is useful for the purpose of withdrawing the noose as soon as it is detached from the vessel. Various instruments have been invented to obliterate the artery leading to an aneurism, by producing the same effect as the application of the ligature. They are mostly constructed on the principle of forceps, and when closed compress the vessel. This method has not been followed in London, and in my opinion is objectionable, because it deprives the patient of the benefit of union by the first intention. If we could avoid the steps necessary for exposing the artery, and the pain of the knife, then there would be some kind of reason for the practice in question; but as the operation of laying bare the artery must be performed, it seems to me better to employ the ligature than any *presse-artères*, and then to bring the sides of the wound together, so as to afford the best chance of union by the first intention. This plan seems to me much wiser than that of leaving in the wound a metallic instrument, which would completely interfere with union by the first intention, without any circumstance of superiority over the ligature as a compensation for so great a disadvantage.

When the artery is tied, according to the principles which I have been attempting to explain to you, secondary hæmorrhage is very rare, unless the artery happen to be diseased

at the part exposed in the operation, or there be some unfavourable circumstance in the health, producing extensive suppuration, or a phagedenic state of the wound. Sometimes, as I have already apprized you, nearly the whole of the arterial system is in a morbid state from the deposition of calcareous matter, and then of course the patient will be likely to have secondary hæmorrhage, though the operation be performed in the best possible manner.

Sometimes the tumour, instead of being quietly removed by the action of the lymphatics, is attacked by inflammation; abscesses form, and purulent matter may then be secreted in the tumour. In such a case it is useful to remember, that though there be suppuration, and you are obliged to open the swelling, much fluid blood seldom issues from the cavity where the pus is lodged. There is generally a copious discharge of matter from it, blended with coagulated blood; but there will usually be little or no loss of fresh blood. However, I do not wish to deceive you with generalities, and the truth is, that now and then hæmorrhage will take place under these circumstances, and a case was mentioned to me the other day by a friend, who had operated for aneurism in the ham upon a patient in the St. Marylebone Infirmary. The leg mortified; a considerable quantity of matter formed in the ham; and when the sloughs loosened, a profuse hæmorrhage followed. About twenty-four hours after the loosening of the sloughs, I saw the surgeon who had done the operation, and at that time the patient had lost upwards of thirty ounces of blood, and was sinking. But this is an unusual circumstance, and for the following reason:—when the whole tumour inflames, and matter forms within it, there is generally more or less coagulable lymph poured into the sac, which obliterates the communication between the artery and the cavity of the aneurism; and, in fact, if such inflammation had taken place before the operation, there would probably have been no occasion for the latter proceeding at all, as a spontaneous cure would have taken place. This subject, however, I explained in a former lecture.

Sometimes the artery will bleed in the situation where the ligature is applied, and, in such a case, it is not always necessary to cut down to the artery and tie it again; for occasionally after the loss of six or eight ounces of blood, the bleeding will stop of itself, and frequently when this is not the case, the application of cold and gentle compression will succeed in stopping the hæmorrhage; but should these means also fail, it would be necessary to take up the vessel again.

After the operation, the patient should be kept perfectly quiet, and above all things, care should be taken not to reduce the temperature of the limb; cold lotions and leaving the limb uncovered, are therefore objectionable practices. In the winter-time, it is the custom of

many experienced surgeons to cover the limb with flannel. I have seen several cases in which mortification followed the indiscreet exposure of the limb to too low a temperature, that is, mortification of a portion of the foot, without the mischief proceeding further; and there is great reason to believe, that after operations for the cure of aneurism, disagreeable consequences often result from not paying proper attention to the temperature of the limb.

Gentlemen, there is one method for the cure of aneurisms, which I have not yet mentioned to you, namely Brador's. It sometimes happens that an aneurism is so situated, that you cannot apply a ligature to the artery leading to it; this is the case with certain subclavian aneurisms, and some aneurisms in the groin and neck. Consequently, such instances cannot be cured by any of the plans I have yet described, and a ligature cannot be applied between the swelling and the heart. As the cure of aneurism depends on the retardation or stoppage of the flow of blood through the sac, Brador imagined it possible to prevent this flow from going on, by applying a ligature on the vessel after it had quitted the aneurismal sac, or on the *distal* side of the aneurism, as the phrase is. However, Brador never performed this operation himself, but it was afterwards attempted in France by Deschamps; but he did not succeed in properly securing the artery, and the merit of the experiment was not really put to the test. The first person, who truly performed this operation, was Sir Astley Cooper; the case was an inguinal aneurism, and the artery was secured below the tumour; however, the operation was not attended with success, for the patient went into the country, and afterwards died of a rupture of the aneurism. Mr. Wardrop since took up the subject, and he deserves great praise for having ascertained in some measure, how far the plan is applicable to certain descriptions of aneurisms. He found, that in some carotid aneurisms this way of operating would answer; and it must be acknowledged, that the common carotid is most favourably circumstanced for this method of operating, as it gives off no branches, and therefore it is not likely that any strong current of blood will continue through the sac. But when an artery is tied on Brador's principle, and any branch of consequence is given off from it between the sac and the ligature, of course the current of blood will still go on through the aneurismal cavity. On this account, it may be conceived that the operation cannot be well adapted to subclavian aneurism, as several considerable vessels would originate between the sac and the ligature. Neither may it appear very promising for inguinal aneurism, because it is hardly possible to apply the ligature above the origin of the profunda, through which artery there would be nearly as great a current into the aneurism as before. However,

notwithstanding these reasonings, there is yet much to be learned on the subject from experience; for we find, that a ligature applied to the subclavian artery is alleged to have cured an aneurism of the arteria innominata. I believe, not less than three cases are on record in proof of this important fact. Here the operator calculates, that the obstruction of the current, produced by tying the subclavian artery, added to that arising from deposition of lamellated coagula in the sac, would interfere so effectually with the circulation in the aneurism, as to bring about a favourable termination. Such are the principles on which the operation has been performed, and, as is reported, in three instances with success. One of these cases, I believe, is sometimes disputed, there being equivocal circumstances about it; but the two others have every appearance of being genuine aneurismal diseases. The case which was cured by Dr. Mott, of New York, seems to be perfectly unobjectionable. However, as I have remarked, further experience is required, in order to be able to give a positive opinion on the question, how far the operation should be extended to different aneurisms. For Mr. Wardrop's researches we ought to feel grateful.

You would suppose, that after the application of a ligature to an artery leading to an aneurism, a great number of the anastomosing branches would become enlarged and remain so. The fact is, that they do enlarge in great numbers; but it appears that, after a time, the number of these enlarged branches is lessened, and at last the circulation is carried on only by a few of these increased channels, and, if we inspect the limb after death, the number of the principal enlarged branches is not great, though conspicuous. Sir Astley Cooper has published an interesting paper on this subject in the *Medico-Chirurgical Transactions*, to which I refer you.

I will now, gentlemen, say a few words on the subject of aneurisms of the aorta, though I believe this is a topic rather out of my province, and that it belongs more properly to the medical lecturer. The aorta, as I have mentioned, is particularly subject to aneurisms, especially in its arch. The aneurisms to which it is liable are of several kinds. The first is the *simple dilatation*, which Scarpa does not consider aneurismal: the tumour involves the whole circumference of the vessel, is generally more or less oval, and never contains lamellated blood, except when some portion of the internal coat has given way; but then, it is scarcely necessary to say, the case would no longer be one of simple dilatation. Here is a specimen of *simple dilatation* of the aorta. The next case is the *true aneurism*—that which includes all the coats of the vessel. The third variety is the *false aneurism*, where the internal and middle coats have given way, and sometimes the external one also; but writers generally mean by a false aneurism a case where the two internal coats have given

way, whether the cellular one has done so or not. The fourth variety is particularly rare; in which the internal coat protrudes through the external ones in the form of a sort of hernia: preparations illustrative of this form of aneurismal disease are preserved at Paris in the collections of Dupuytren and Dubois. Some authors reckon a fifth variety of aortic aneurism, namely, the case where a false aneurism becomes engrafted on a simple dilatation: I think this may be an unnecessary distinction.

The dilatation or enlargement of the whole circumference of the aorta is generally attended with an atheromatous or calcareous deposit between the internal and middle coats; and when you do not observe this change, you will generally remark, that the internal coat is opaque and friable, and is more inelastic than natural. The ascending portion of the aorta is most subject to simple dilatation, as you see in this preparation; but other parts of it may be thus affected, and sometimes several portions of it at once, so as to give the vessel the sacculated appearance of the transverse arch of the colon. The dilatation seldom exceeds twice the natural diameter of the aorta; and when it is examined in the dead subject, it is not so conspicuous as an aneurism, the artery having become flaccid,—a circumstance well explained by Scarpa.

Now, this dilatation of the aorta does not generally give rise to much inconvenience; it does not, like an aneurism, press on any important organ so as to derange its functions; it is an oval tumour, and its pressure is more equable and yielding. The effects of the pressure of an aneurism may be fatal, but this is never the case with the simple dilatation. The worst consequence, produced by the latter, is a degree of difficulty of breathing, from the tumour touching the trachea or bronchi; for these organs are so irritable, that pressure on them readily excites dyspnoea, which is usually the worst symptom, as long as the disease remains a simple dilatation; for you should understand, that generally this affection leads to an enlargement of the heart, and then the two diseases together give rise to more serious consequences.

True aneurism of the aorta differs from a simple dilatation of that vessel, in its occupying only a part of the circumference of the vessel. It is generally situated on the front or lateral parts of the arch, never on the posterior surface of the vessel, and never on its lesser curvature. It differs from a dilatation in another important point, namely, in the communication between the sac and the artery being a contracted, narrow, and abrupt opening. In the simple dilatation, the blood is still flowing in its natural course; but, in aneurism, the contrary is the case. In almost all aneurisms of the aorta, especially of the descending aorta, however large they may be, you will find that the vessel itself is not increased in size, and the aneurism is merely like a swelling engrafted on the vessel.

The *false aneurism of the aorta* is that in which the internal coats have ulcerated or given way, generally in consequence of a pulsatous, atheromatous, or calcareous deposition between them; then the cellular coat forms the immediate covering for the blood; and when it also gives way, the surrounding parts, which have been thickened in consequence of the pressure of the tumour, contribute in their turn to make the interior of the sac.

With respect to the symptoms of an aneurism of the thoracic aorta, if we put out of consideration those cases, which have advanced so as to be attended with a swelling externally, there are no symptoms which are completely unequivocal. As for the difficulty of breathing, the cough, disturbed dreams, anasarca, and oppression of the chest, these complaints may all of them depend on organic disease of the heart; so may intermittent pulse, as well as hæmoptysis, which is an occasional effect of an aneurism of the thoracic aorta. All these signs, gentlemen, are ambiguous. We generally find, however, that when the aneurism is of the ascending aorta, that there is a kind of purring tremor at the sternal ends of the clavicles—the *frémissement cataire* of Laennec. This is more particularly indicative of the simple dilatation, for in this there is no coagulated blood in the sac; whereas, in aneurism, the coagulum prevents the vibrations of the pulsation from being so perceptible. You may also remark, that when the chest is struck, it emits a dull sound; it does not feel so hollow as when there is no aneurismal tumour occupying it; but one of the strongest symptoms, next to the projection of the tumour externally, is the peculiar sound emitted by the entrance of the blood into the sac, it is a sound different from that caused by the heart's action, it is louder and more abrupt, and when using the stethoscope, you will be able to observe, that as you approach the heart, the sound diminishes; this sound has been compared to the noise of the rasping of wood at a distance. Those who are skilled in the use of the stethoscope know very well the difference between the sound of the heart's action and that of the aneurism.

In the abdomen, aneurisms of the aorta do not always produce symptoms so afflicting as those produced by the disease when it is in the thorax; and this circumstance is explained by two facts: in the first place, the tumour in the abdomen is not confined in a bony cavity; and in the second place, the viscera of the abdomen are capable of bearing certain degrees of pressure, without such dangerous consequences as those which inevitably arise from pressure on the thoracic viscera. The situation of the œsophagus, the lungs, the heart, the pneumo-gastric nerve, and the thoracic duct, explains the greater sufferings and danger commonly attending thoracic aneurisms.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XIII.

Phthisis—Value of Chlorine Inhalations—Bronchitis—Pleuritis—Dropsy treated with Iodine—Dysphagia.

GENTLEMEN.—We have two cases at present in the hospital, which have been for some time under the use of chlorine inhalations. The patients are, as you are aware, labouring under phthisis, and I need not say, that in subjecting them to this mode of treatment, I did not set out with the expectation of their deriving any considerable and decided advantage, for the cases were at the period of their admission essentially hopeless. They had all the symptoms which, as I mentioned to you on a former occasion, pointed out the incurability of phthisis. In the first place, there was in both not only symptoms of phthisis but also a confirmed hectic, a circumstance which is indicative of much more extensive disease than the occurrence of mere suppuration in the lungs. This is a point to which I would direct your attention. In pulmonary diseases we often find that hectic symptoms are connected *more with the extent and incurability of the disease than the mere presence of matter in the lungs*, and hence it is that we frequently see hectic coming on before the actual suppuration of tubercles. On the other hand, you will see numerous instances of tubercular cavities without hectic. We often meet with patients who have symptoms of abscess in the lungs, with intense bronchitis and other very urgent symptoms, and we frequently find, that by treatment calculated to subdue the bronchitis we are able to put a stop to the hectic, although the suppuration still goes on. You will be called to attend persons in consumption, who are labouring under hectic fever, and on inquiry you may find that they are using wine and animal food; put them on milk diet, and you will often observe an extraordinary improvement in the febrile symptoms, though there is no amendment, so far as suppuration is concerned.

In the other case of phthisis, where chlorine inhalations have been used, there is disease of the larynx, and in both we have evident symptoms of derangement of the digestive organs, so that every circumstance tends to render them cases in which very little can be accomplished. I have put them, however, on chlorine inhalations, more for the purpose of observing its effect on the system than from any hope of deriving advantage from its employment. You are aware that this remedy has been recommended by many practitioners, and by none more particularly than Cotteran,

who published a memoir on this subject in the "Archives Generales de Medicine." The reason why I direct your attention to this subject is, that there are statements put forth in that memoir which I have not been able to verify. Cotteran states that he has treated cases of phthisis successfully by means of the chlorine inhalation, and he professes himself to be a stethoscopist. If a man who is not a stethoscopist states that he has cured phthisis, the question is then less as to the curability of the disease than the correctness of the diagnosis; but when a stethoscopist tells you that he has cured cases in which there have been hectic symptoms with cavernous respiration, and dulness of sound on percussion beneath the clavicles, it is certain the case is altered. Now he states that he has treated several cases successfully, and brings forward instances of decided cure. I shall make no comment on this, but shall only mention that in this hospital we have treated a great many cases with chlorine inhalation, and I regret to say the results have not been such as to enable us to recommend its use. In a few cases it has effected some slight good, in several we have done positive mischief, and in the majority of instances we have done neither good nor harm. You remember I mentioned to you on a former occasion that the essence of this plan of treatment is simply this, an attempt to cure chronic inflammatory disease by stimulation. The principle appears to be just the same as that by which chronic mucous discharge from the urethra is cured with balsam copaiba, or chronic diarrhoea is cured with turpentine. Besides, you are to bear in mind that you always run a great risk in those cases where you have to deal with an extensive organ such as the lung. In phthisis the expectoration is frequently very copious; there is an immense secretion going on, which may in some degree be looked on as a relief to the inflammatory action. If you check this secretion, you will find that the patient's sufferings are intense, and that matters are in a more unfavourable condition than before. This principle, gentlemen, applies to every case of direct stimulation. Where the chlorine inhalation had a tendency to diminish expectoration, we found that it was followed by very unpleasant symptoms, such as those which occur when you suddenly check a chronic diarrhoea, or any other continued discharge. We observed that where the spitting was suddenly diminished, the result was intense dyspnoea, fever, pains in the chest, and the stethoscopic signs of pneumonia in the lower part of the lung, which had been previously free from disease. In two or three cases the symptoms of pneumonia were so violent that we were obliged to have recourse to venesection. We also noticed that when the inhalations were discontinued the patients in a few days returned to their former condition.

There is another circumstance connected

with this practice which is worthy of remembrance. In many instances it appeared to produce a kind of revulsion from the chest to the abdominal viscera; the cough and expectoration were lessened, but diarrhoea or vomiting came on, and the patients seemed to have gastritis. The reverse of this has often been observed, as in cases of long continued diarrhoea, in which by treatment with astringents and stimulants, the discharge has been suddenly checked. We then may see a violent chest affection come on, and a most copious secretion established from the bronchial mucous membrane. Another curious fact is, that the inhalation very frequently produced a state of stupor, the patients appearing to be as it were under the influence of narcotics. I have seen persons fall asleep with the pipe of the inhaling instrument in their mouths. I do not know, however, how far we are to look on this agent as a narcotic, but it certainly produced effects very similar to those which arise from the use of soporific medicines.

This, gentlemen, is the sum of our observations on the use of chlorine inhalation in phthisis. Most of the cases in which it was employed were unfavourable, and there was, for the most part, distinct evidence of disease of the digestive system. If we could have tubercular abscess without disease of the digestive system, or a scrofulous habit, it might do very well. On the other hand, we have derived remarkable benefit from the use of chlorine in a case of gangrenous abscess of the lung which was in the hospital some time since. The patient was an unfortunate man who in a state of beastly intoxication rolled out of bed quite naked, and lay all night on a damp floor. He awoke in the morning extremely ill, with severe pain in the side he was lying on; fever set in rapidly, his breathing became very much affected, and he began to cough up a quantity of dark foetid matter. He was admitted into the hospital with the stethoscopic signs of a cavity in the left lung, severe hectic, breath and expectoration extremely offensive. He was ordered to have wine, nourishing diet, and chlorine inhalations. After the lapse of twenty-four hours there was considerable amendment, and after forty-eight the foetor was greatly diminished, and on the third day the smell ceased to be offensive to persons in the ward. In order to ascertain if this was the consequence of using the chlorine, we ordered it to be omitted for a day or two, and found that the foetor again returned, but after recurring to its employment the breath improved a second time. On this plan of treatment we kept him for some days, when the stench of the expectoration and breath having entirely ceased, we omitted it altogether. All the gangrenous symptoms returned again, and a third time were removed by the chlorine. It was the internal use of the chloride of lime we employed on this occasion; latterly I have been trying the chloride of soda. It has effected a most decided good

in the case, and indeed if we derived no other advantage from its employment beyond that of correcting foetid breath and offensive expectoration it is certainly a very material point, for there is no stench in nature more disgusting than that which attends gangrene of the lung, and I am confident a great deal of good was done by correcting this foetor, and preventing the absorption of putrid matter. I would advise you, therefore, in every case of mortification of the lungs, to direct your patient to use a good, nutritious diet, and make him constantly inhale an atmosphere of chlorine, by keeping his bed sprinkled with a solution of chloride of lime, and having a vessel containing the solution beneath. You should also take the trouble of ascertaining how the inhaler is used, for some persons draw the chlorine into their mouths only as they would tobacco smoke, and do not let any of it pass into the lungs; it is necessary to show them how to use it, and make them understand that the entrance of the chlorine vapour into the chest is indispensable.

There are two cases, gentlemen, in the upper wards which demand some few observations. One of them is the case of a man named Lindsay, which has been for some time under the care of Mr. Aston, and affords a very good illustration of a general pathological law. Whenever a person has local chronic irritation in any of the viscera, let that person chance to get fever, and you will generally find that the original local disease will be very much exasperated. This man had a chronic bronchitis at the time of his admission; he afterwards got fever, and you have seen how much the affection of the chest has increased in violence. You will always do well, when attending a case of fever, to inquire whether the local disease be of a chronic nature, as it makes a very material difference whether the complaint be of recent origin or not, and it is of importance that you should be aware of this.

The other case to which I alluded is one of considerable interest; it is a case of severe inflammation of the right pleura, and is important in another point of view as being illustrative of the diagnosis between disease of the pleura and hepatitis. This man presents the stethoscopic phenomena of effusion into the right pleura, he has dilatation of the affected side, and elevation of the intercostal spaces, absence of the respiratory murmur at the lower part of the right side, and no resonance of voice; and the absence of vibration in the chest when the patient speaks is here very well marked, for if you place your hand on the left side of his chest, and make him speak in a full tone of voice, you feel the vibration of the chest produced by the resonance of the voice on that side, but at the right side, where the fluid exists, this phenomenon is completely absent.

This is a case, gentlemen, which I cannot look on as an ordinary inflammation of the

pleura; the patient is in a very low state, his condition is evidently typhoid, and gives you an instance of what the older authors used to term bilious pleurisy. In addition to the pleuritic affection, he has well marked gastric symptoms, and I think we may call his disease typhoid pleuritis, in the same way as we term inflammation of the parenchymatous tissue of the lung with gastro-enteric complication and a low state of system, typhoid pneumonia. This typhoid pleuritis requires the same attention to the gastric affection as the typhoid pneumonia, and we generally observe that, in such cases, the abdominal symptoms can never be overlooked with safety. On Saturday we applied leeches to this man's epigastrium, as well as to the affected side, and to-day there is some amendment. I have to reiterate here an observation made on a former occasion, with respect to pleurisy, that, in Dublin, simple acute pleuritis is a very rare disease. We frequently meet with other forms of the disease in the simple state, but very seldom this. I remember, that at one time, for nearly the space of three years, we did not meet with an instance of œgophony in the hospital, except one in the case of a baker, who had pleuritis, not as the effect of cold, but produced by an injury from a fall. With this exception we had no other opportunity of observing the phenomenon of œgophony during the period above mentioned.

Since our last meeting there has been a case of dropsy here, under the care of Mr. Franklin, in which we have been employing the iodine mineral water. The patient was a man employed about stables, and frequently exposed to cold, wet, and hardship, in carrying water and washing carriages. He got cold, became very ill and weak, and anasarca of the lower extremities followed. As the case was clearly of a low asthenic character, we thought the best chance we could give him was to put him on the use of iodine. To-day, as you may have observed, he has been ordered some aperient medicine, and this is a matter of importance, and should never be neglected. The lower and weaker a case of this kind is, the more care should you take to prevent fecal accumulation, as, by pressure on the abdominal veins and absorbents, it may bring on an increase of dropsy. We sometimes observe that weakly old persons get anasarcaous limbs when their bowels are confined, and that the swelling disappears after taking purgative medicine. The weaker, therefore, a person is, the greater attention you must pay to evacuate the bowels, as without this precaution you will accomplish but very little good with the iodine.

The last case, to which I shall draw your attention, is one of exceeding importance; it is the case of dysphagia, under the care of Mr. Tuite. Dysphagia, gentlemen, is produced by affections of many and various organs, and consequently conveying many and different meanings. We have it, for instance, arising from affections of the mouth, tongue, and fauces; we have it proceeding from disease of

the epiglottis and larynx. You all know, that where there is disease of the larynx every attempt to swallow gives great pain, and here we observe dysphagia unconnected with any disease of the apparatus employed in the trajet of the food. In the next place, we may have it in consequence of any disease of the œsophagus. Inflammation of any muscular organ like the œsophagus produces, in the first place, spasmodic action in the affected part, in the next place, vascularity and tumefaction, and lastly, the sensibility of the part is so excitable, that when a morsel of food touches it, pain and dysphagia are the necessary consequences. Again, it may depend on chronic inflammation of any part of the œsophagus, and this you should bear in mind, as it is connected with the history of the organic stricture of the œsophagus. You are not to expect an easy cure in such affections, and you can readily understand the reason of this. If they are to be cured or relieved, it is by means calculated to relieve irritation and remove chronic inflammation. There is a strong and close analogy between inflammation of this kind and that which attacks the submucous tissue of the intestinal canal. The same vascularity, the same thickening is observable in both; we see it in the pylorus and other parts of the digestive tube, and so it is with respect to the œsophagus. This view of the subject gives you a key to the treatment in every stage of the disease.

In the next place, gentlemen, we may have dysphagia from various kinds of tumours. The internal surface of the œsophagus is subject to cancerous, morbid, and fungous growths. It may arise, too, from tumours situated external to the tube, the most ordinary instances of which are abscesses, bronchocele, disease of the spine, forming a protrusion anteriorly, and aneurism of the aorta, or some of its immediate branches. There are many instances of aneurism of the aorta compressing the œsophagus, and finally bursting into that tube, so that the patient dies of a vomiting of blood from this cause, as I have seen in private practice. I recollect the case of a woman, who was here some time back, having been admitted with the symptoms and usual stethoscopic phenomena of phthisis. She had dulness of sound on percussion below the left clavicle, and over a great part of the left lung, bronchial respiration, and hectic. In addition to these symptoms she complained of constant dysphagia; she said that the food always stopped at a certain part of the œsophagus, and there produced considerable pain and difficulty in swallowing, but when it had once passed this point there was no further obstruction. On the third day after her admission she died. We opened the chest but could not find either abscess or tubercle. We found the lung did not occupy the upper portion of the chest, near the clavicle, its situation was filled by an immense tumour of the encephaloid kind. It was this which oc-

casioned the stethoscopic phenomena of dullness of sound on percussion, and absence of the respiratory murmur. It extended also to the mediastinum, and sent out from its posterior surface two projections, which pressed against the œsophagus, and caused the dysphagia. The last cause of dysphagia (and it is a frequent and important one) is inflammation of the cardiac orifice of the stomach.

Let us now, gentlemen, with these views, come to the analysis of the present case. Mr. Chuite has, with his usual accuracy, drawn up a history of the case, of which the following is an abstract:—Edward Lynch was attacked ten days before admission, with pain in the back, and stitches at the lower part of the sternum. These continued for a week, when he first felt a soreness on swallowing, which increased so much that on the following day he could swallow no solids whatever, the attempt producing great pain, and a sense of weight, followed by hiccup and vomiting. He has frequent eructations with relief of the sense of oppression. Since the occurrence of the dysphagia he has lost his appetite; there is some epigastric tenderness; bowels costive since the commencement of his illness; his general appearance is that of a man labouring under low gastric fever. On examination, by the stethoscope and percussion, no morbid phenomenon could be detected, *except that the respiration over the whole of the right lung was feeble as compared with that in the left, no sound continuing clear on percussion.* On the day after admission, Mr. Porter passed a probang without meeting any obstruction, but the patient complained of soreness at the seat of stoppage.

Before the probang had been used we considered that the irritation was very low down, from the statements made by the patient himself. This morning he says he feels better, but as yet he has not attempted to swallow fluids. We have observed, that some minutes after he has swallowed a morsel of food, symptoms of irritation of the stomach come on, he begins to eructate; and goes on in this way until he gets up a small quantity of frothy fluid.

We have now, gentlemen, to investigate the cause of this disease. Before we proceed to this, I have to remark, that, in enumerating the causes of dysphagia I forgot two very important ones—spasm and paralysis of the œsophagus. In the first place, let me remind you of all the known causes of the disease. These are affections of the mouth, pharynx and larynx; inflammation of the œsophagus, either acute or chronic; tumours external or internal to the œsophagus; spasm, and paralysis of that tube. Now for the symptoms in the present case. In the first place, the diagnosis of this case is involved in considerable difficulty, from the recent nature of the attack. It appears, however, certain, that it is not a case of disease of the mouth, or fauces, or larynx, and here we have got rid of three causes. In the next place, we have no direct

evidence of the existence of a tumour pressing on the œsophagus. In the great majority of cases of tumours the swelling is apparent where it is external to the œsophagus, and can be detected. With respect to aneurism or abscess, which are more difficult to be detected, we cannot conceive how they could have possibly formed in such a short space of time. It might, however, be occasioned by any of these three causes; but the probability is, that it is not a case of dysphagia produced by any kind of tumour pressing on the œsophagus; and this probability is still further increased, when you recollect, that to day this man can swallow better. He has taken a large quantity of fluid at a time without experiencing any difficulty or obstruction to its passage, and this could scarcely happen if the impediment was caused by a tumour, nor would his relief be so sudden; and to this must be added, the fact of not finding any obstruction on passing the probang. Considering, therefore, the recent nature of the disease, and *the sudden improvement in the power of swallowing*, I think we may put aside the opinion, that in this case, the dysphagia arises from the pressure of the tumour. In the next place, does it arise from a tumour in the œsophagus? I should rather think not; because in the great majority of cases, where dysphagia has been the consequence of tumours within the œsophagus, the disease has been chronic. Such instances take a considerable time in forming; the dysphagia comes on slowly and gradually; and in this way attains a great height. But here we have no evidence of the existence of such a cause; and I think we may discard the notion of tumours within as well as external to the œsophagus. What causes, then, have we to investigate? It may be produced by acute inflammation, or by spasm of the œsophagus, or by disease of the cardiac orifice of the stomach.

Now, in the first place, I do not think it is spasmodic stricture of the œsophagus. In cases of spasm the attack comes on with severe pain, which lasts for some time and then subsides; that is to say, pain and spasm always accompany the phenomena of dysphagia arising from this source. But in this case we have *the pain coming on long before the occurrence of obstruction.* As far, therefore, as we can see, it is either acute œsophagitis, or disease of the cardiac orifice of the stomach, or both; and this appears to be borne out by the facts of the case. The patient has the appearance of fever; his look, and the smell which is perceived in the vicinity of his bed, is gastric. Again; he has a morbid condition of tongue; and this morning it has very much the appearance which it presents in cases of gastric inflammation. Then we have distinct evidence of an affection of the stomach. He has flatus, a degree of pyrosis, and loss of appetite, which is not an unfavourable thing under his present circumstances, but is of great importance as connected with this case. If the dys-

phagia depended on spasm or tumour merely, there would be nothing to account for the loss of appetite, as in such cases the patients generally have a desire for food. From a review of all the circumstances which I have enumerated, I am induced to think that it is disease about the cardiac orifice of the stomach; and there is another circumstance of importance, as tending to confirm the notion, that the disease is low down the œsophagus and near the stomach. After he has swallowed a considerable quantity of fluid the stomach begins to sicken, and he has a desire to throw up its contents. Connect this with the relief derived from his treatment (leeching, iced water, blistering, and purgative injections), and you will perceive that the symptoms and the result of treatment agree together. Still, gentlemen, I repeat it,—the case is obscure, and requires a more satisfactory elucidation.

[In a subsequent lecture, Dr. Stokes reverted to the case of dysphagia, which had then terminated fatally. Immediately before death the patient vomited a large quantity of blood. The dissection was performed before the class, when the following lesions were discovered. The cause of the dysphagia was a *small aortic aneurism*, which was about the size of a walnut, and which had perforated the œsophagus, and pressed on the opposite side of the tube, where the lining membrane was inflamed and ulcerated extensively. The aneurismal tumour was merely covered with the cuticular membrane of the œsophagus, which had given way, and it pressed on the right bronchial tube, thereby causing the feebleness of respiration. The cardiac portion of the stomach was inflamed, and the aorta showed marks of extensive recent disease. Dr. Stokes commented at some length on the case, and dwelt on the difficulty of diagnosis, and the fallacy of the use of probang in determining the existence of tumour connected with the œsophagus, and its danger in cases of aneurism, of which this case furnished a striking illustration. He further dwelt on the circumstances observed during the progress of the case, which might be supposed to make for or against the opinion that an aneurism existed. In favour of aneurism were only the fact of its being an occasional cause, the existence of pain under the shoulder, which the patient for a few days before death described as pulsating, and the difference of respiration in the lungs. On the other hand, the absence of stethoscopic signs of aneurism, the want of the usual symptoms of the disease, the free passing of the probang, the partial relief of treatment, the anorexia and appearance of the patient, all were in favour of the existence of disease of the mucous surface of the stomach and lower portion of the œsophagus.]—*Note by the Reporter.*

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S., &C.

At the Westminster Hospital.

LECTURES V. & VI.

ON THE DISEASES OF THE URINARY ORGANS, AND HIP JOINT.

GENTLEMEN,—It is some time since I have had the pleasure of meeting you here for the purpose of continuing our clinical observations. I have been very much occupied on the one hand and rather lazy on the other, being disposed to get through my business as quickly as possible, and amuse myself out of town on an evening whenever the weather would permit, rather than to speechify in this dirty place. We must work the harder in the winter, and we shall be the better able to do so if we come to it in good health and spirits. I recommend you all to go to your friends for a few weeks in August and September, if you have any in the country willing to receive you. A little relaxation is useful to every one. It is a capital thing for an old coach horse, and it is no less so for a young doctor.

I concluded my last observations on the use of the prostate catheter by showing you the instrument, but you must recollect, that it is only particularly serviceable in those cases of enlarged prostate which are distinctly well marked, and occur in elderly men. In those derangements of the prostatic part of the urethra, and of the neck of the bladder, which are frequently met with in younger persons an instrument with a different curve is preferable and passes much more easily. It will indeed pass often with ease when the prostate catheter will not. I call it No. 2. prostate catheter, to distinguish it from the other which is No. 1. It is shorter and straighter, with an inclination to curve at its extremity, rather than actually curving like the other. It has a small wooden handle with two eyes, in order that it may be tied in readily if necessary, and it is strengthened by a stillet of what is called flexible but stiff metal by the instrument makers, having a ring at the end, by which it may be the more readily withdrawn. The instrument I now show you is the third kind I commonly use. It is merely a solid iron round polished, of a particular curvature, having a small wooden handle; the last inch and a half towards the point being gradually diminished in size, so that if the shaft of the instrument be as ten, the point shall be eight. You should, however, have them of the same size throughout, and I have them on the contrary made a little bulbous, an inch or two from the point, for particular use. This third kind of instrument should be plated, or gilt if you please, for dandy gentlemen, which prevents their getting rusty; they also look prettier, and a man submits much more readily to the use of a silver instrument

than he will to a piece of cold steel, however well polished. There is a great deal in imagination in this world, and a great deal more in humbug, and if, after having passed a silver sound some twenty or thirty times for a patient, you finish your proceeding with a gold one I assure you he does not forget it. I do not happen to have a gold one myself, but I think I must get one, for gold for gold is but reasonable.

An instrument of this shape passes through a healthy urethra without stop or stay. It meets with no obstacle when managed by a surgeon conversant with the attachments of this canal, and it passes so easily and with so little pain and inconvenience, that the patient scarcely believes it has been introduced when it has been withdrawn. A well oiled instrument, of a proper temperature, a size or two less than the orifice of the urethra, will pass through it to the astonishment of the patient, when a small, soft, and pointed wax bougie will catch on something at every inch. A gentleman, who had been using himself small bougies of this kind, came up to me from Worcester, declaring he had an impassable stricture, which rendered him miserable, for, although he could make a tolerable stream of water, he never could pass the smallest bougie in his possession, and he had great fears for the result. Finding that he could make a fair stream of water, I selected a No. 8; it went with ease, I then took a 12, it went as easily, a 14 followed as readily. The gentleman declared it was done by magic, whereas it was merely done by virtue of an instrument of a proper shape and size.

The two prostatic catheters should also be made of a soft metal, which is, I believe, called pure tin by the instrument makers. It was formerly a patent composition, or something like it, and bougies were made of it for common use, but I disapprove very much of the construction of small and pointed instruments of any kind of flexible metal, for they are not only apt to break, but to bend and deceive the surgeon or person who is using them, by inducing him to believe they are passing on when they are only bending. I am quite sure, that the greater part of the false passages, which have been made in the urethra, were made by metallic or flexible bougies, and I look upon them as very dangerous instruments; a surgeon always knows what he is about with a solid one, he never knows exactly what he is doing with a flexible one if any pressure be required with it.

There is a great difference in the manner of using a metallic or flexible bougie, or even a common wax one, and a solid sound. I have already shown the way in which this latter is to be managed, and have drawn your attention to the fact of its point mounting, or riding over an obstacle, by the motion which is given to its handle. It is in consequence of this that it surmounts or eludes all the obstacles to be met with in the canal, and which surgeons

have been pleased to call natural, but which are really only called forth by the use of an improper instrument. The round point of a solid sound, or bougie, is always readily carried along, or borne against, the upper surface of the urethra, the point of a flexible instrument will almost always and unavoidably be carried along the under surface of the urethra; and as all the parts, which can cause obstruction, except the lacuna magna, are to be found on the under part, it must necessarily meet more readily with them, especially as the passage of the flexible instrument is effected by a steady pressure of the finger and thumb, without any but a forward motion being communicated to the point. This is the cause of the frequent failure of a soft or flexible bougie, whilst a solid one will pass with ease; but you must be made aware, that when the curve of the solid bougie does not correspond with the opening of a stricture, and which occurs most frequently in short persons, in whom the curvature of the canal is greater for their size than in taller persons, a soft wax bougie will often pass much more readily, and is to be preferred. I have a gentleman at this moment under my care, who has had a stricture for thirty years, and is a great performer with metallic bougies, he cannot pass his metal one at all now that the stricture is narrow, whilst I can pass a soft wax one, of the same size with ease. This he cannot comprehend, and I will not tell him why. Metallic bougies, then, I do not use, metallic catheters I do in certain cases, but only in them, relying in all others on solid instruments, which will not easily break, and do not readily deceive us as to their motions and the progress they are making.

You should have two kinds of wax bougies for use, one soft, so as to be capable of taking an impression with ease, the other made of harder materials, so as to take any form you please when slightly warmed, but which still opposes a good deal of resistance to pressure. Catgut and elastic gum bougies, of various sizes, will complete your common surgical apparatus. Of other and more complicated ones we shall speak when we have noticed the remaining part of the urethra, and the diseases for which they are especially intended.

There have been some cases of injuries of the hip, to which I wish to draw your attention while the remembrance of them is fresh in your recollection. The first to which I shall allude is a case of dislocation into the ischiatic notch, which was in the hospital some months ago. This occurred in a woman; the second of the same kind took place in a boy a short time back. Such accidents are unusual, and still less so in females and children. You may attend an hospital for a whole life, and not see the like again in any one year. The woman was brought into the hospital, having fallen in a struggle with some of the police, and the late apothecary brought the limb into its proper place. It was soon, however,

found out of it, was again restored, and so on for a fortnight, during which time it became an object of speculation. Some said it was a fracture, others a dislocation, and a third said they did not know what it was. At this time I was asked to look at it, and, as the swelling had in some degree subsided, I had no difficulty, in a moment, in declaring it to be a dislocation into the ischiatic notch. The patient was turned over to me, and after a steady extension of some thirty minutes, the head of the bone began to alter its position, and was finally reduced.

The boy was admitted into the hospital one evening during my week, and the subsequent morning I visited him. Several speculations had been hazarded on this case, also, and in favour of fracture. You all of you know, and the home-surgeon, Mr. Finch, especially, that I equally decided in a moment what it was and instantly desired he might be taken into the theatre for its reduction. The way in which I state this to you may induce some of my friends to believe that I wish them to suppose I possess a peculiar tact in distinguishing injuries of this part from each other. Now, I possess nothing you may not acquire on the same terms; and if, as you have seen, I have been able to distinguish these injuries more readily than you might have supposed, from what you hear and what you read, I pray you lose no time in obtaining the same information. It is simply by studying closely the anatomy of the parts in a similar way. When I was in Spain and Portugal I always had a dissecting room whenever I had a hospital, and in this or these the attentive fellows used to work with me and for me, as some of you did last winter, and will I hope do in the ensuing one.

Previously to the siege of Ciudad Rodrigo, I had a place of this description in a village on the Portuguese side of that town, called Aldea del Obispo, in which I practised every possible mode of amputating the thigh at the hip joint, and then of dissecting the cut parts afterwards, and particularly those which adhered to the pelvis. The method usually adopted in dissection, of following the whole course of muscles, is a good one for one purpose, but not for that of studying joints, and particularly the hip and the shoulder. A thorough knowledge of the muscles which surround them can only be obtained in the way I have mentioned, and then by re-applying the bones to each other, you will understand their situation and their derangements better than in any other way. The situation of the head of the femur when in the acetabulum is immediately in a line extending downwards from the anterior superior spinous process of the ilium; here you have to seek for it in amputation, and when a dislocation backwards takes place, there is comparatively nothing to fill up its place and that of the neck of the bone which have been removed with it. The trochanter major is not so much shifted from

its situation as you might suspect, but a different part of it is turned towards you, and you can feel that it is a different surface when you examine first one side and then the other. This is not, however, so important a mark as a small hollow, which the absence of the neck of the bone leaves in front of it, which I consider a very diagnostic hollow, and which you do not meet with in the only fracture which can simulate these dislocations. The head of the bone in any reasonably fat person can also be felt if the limb be rolled from the knee in the ischiatic notch. In these two cases, then, I did two things; I first rotated the thigh with my finger in the little hollow alluded to, and then with my thumb on the trochanter, and the two first fingers on the part where the head of the bone must be according to the distance between these parts. The motion of the head of the bone was distinct, and the ascertaining the fact did not occupy a minute. Now for other signs. The limb was a little, and only a little, shortened; the great toe rested upon the other great toe, because the knee was turned in, and this turned in because the great trochanter was turned inwards, and the head of the bone backwards and outwards. As the head of the bone was backwards, the lower part of the thigh was necessarily inwards, whilst the muscles attached to the trochanter minor would raise or draw it forwards or bend the body. The person to whom this accident has happened stands on one foot, with the body a little bent, the thigh advanced and turned inwards, the great toe of the affected side resting on the other; turn him round, and the greater width and deformity of the buttock is very apparent; examine him in the way I have described as the nature of the injury becomes manifest. The only fracture which resembles this injury in the least, is that particular one of the dissection of which I have given an account in the *Medico-Chirurgical Transactions*. In this case the toe turns inwards and the leg is a little shorter, but there is no hollow in front of the trochanter, there is no head of the bone to be felt rolling in the ischiatic notch. I should add, that the head of the bone in these cases is at the upper part of the notch and not the lower, if it were otherwise the limb would be longer instead of shorter, at least I suspect so, for I have never seen the case. It is said that in dislocation there is no motion, whilst in fracture there is a great deal, but this must be received with caution, for you all saw that in these two cases there was a great deal of motion, and I do not think that much dependence can be placed on this sign, except as far as regards the elongation or shortening of the limb, which in dislocation is always the same, but varies in fractures according to circumstances. The mode of reduction, and the principle of doing it are both simple, although this has been considered a most formidable injury to treat. The

head of the bone is carried behind, and a little above, the acetabulum. The person should be placed on the sound side, and the counter-extension should be made in the direct line or axis of the body. The knee of the affected side is then to be drawn across the lower part of the opposite thigh. In both the cases I used the pulleys, and you saw my fore-finger rest on the head of the bone, and marked its gradual motion downwards and forwards to the raised edge of the acetabulum. To get it over this, I rolled the knee a little with my other hand in order to move the head of the bone, and thus facilitated its yielding to the extending power. I also desired the thigh to be raised upwards by a roller placed around its upper part so as to separate if possible the head of the femur from the dorsum of the acetabulum, and the dislocated parts were restored to their places, but in a very different manner in each. In the woman where the extending power required was great, the head of the bone was drawn into its place by it alone, and not apparently by any exertion of the muscles, which frequently right themselves as the part is restoring, and by a spasmodic effort draw the bone into its place. As the head of the femur passed over the edge of the acetabulum, the feeling conveyed to my finger which rested upon it, was that of the crushing of the cartilaginous edge which deepens the cavity. It was something very peculiar which I never felt before, and led to the suspicion that this edge had been broken off at the time of injury. It is possible that this may also have led to the supposed frequency with which the head of the bone had slipped from the cavity. It was a long time before this woman recovered; low inflammation followed in the joint, and considerable thickening around, supporting the belief that the cartilaginous labrum of the cavity had been injured in an especial manner.

In regard to the boy, the bone slipped into its place, with a snap heard by all around, showing the action of the muscles. I was never more satisfied with any thing in my life. The dislocation was reduced in less than five minutes, and without leaving a mark showing where a bandage had been applied, and the boy left the hospital in a fortnight.

I hope you have observed with great attention the fracture of the great trochanter and neck of the femur, treated on Mr. Amesbury's bed in Percy Ward. The man has recovered without any deformity, and with much more comfort to himself than by any other apparatus with which I am acquainted. If I should have the misfortune to break the neck of my thigh-bone, I will be placed on Mr. Amesbury's fracture apparatus, and, if possible, I will be treated by Mr. Amesbury himself.

OBSERVATIONS ON THE CHARACTER AND TREATMENT OF IRITIS.

BY CHARLES WARBURTON RIGGS, ESQ.
SURGEON.

INFLAMMATION of the *iris* may be considered as *simple* or *specific*, as it comes on in a healthy state of the system, or arises during the existence of what are called specific or constitutional diseases. Another division into acute, sub-acute, and chronic, must not be omitted. The epithet *sub-acute* conveys a more accurate idea of the slower forms of this affection. The term *chronic* denotes, in the general acceptation, the condition that remains after the subsidence of active inflammation, or a slow and irregular species of inflammatory action. Cases of *iritis* are not frequent, and practitioners are not, it is feared, sufficiently acquainted with the disease, so as to discriminate the first indications of the affection, when the inflammation can in almost every case be arrested. My object in drawing up this article has been to lay before the numerous readers of this journal a brief treatise on *iritis*, containing the opinions of the most approved writers and teachers, with deductions from a pretty extensive opportunity of observing the affection, and of acquiring the collateral information that the subject naturally embraces. I cannot better convey or more forcibly express the necessity of being able to recognise the earliest marks of *iritis*, and the ignorance and inattention that prevails in detecting the primary stage of the disease, than by reciting the following case.

A young gentleman, about thirty, complained of general uneasiness of one eye, pain of the ball and inflammation. These symptoms were first experienced towards evening, and abated much before morning. The next day, about the same hour, they recurred with increased severity, the pain extending to the orbit and temple. The medical attendant to the family now saw the person, and found the vascularity so slight as to lead him to con-

sider the attack as one of rheumatism of the sclerotic. Four days elapsed with progressive aggravation, the pain towards evening becoming intolerable, with great intolerance of light. The violence of his sufferings, and not any apprehension of the deprivation of his sight, induced the patient to have additional advice. *Iritis* was then detected, barely in time to preserve vision under the most decisive treatment.

The necessity of being able to recognise the complaint on its invasion is too apparent to dwell on. This is the leading difficulty to be encountered. If the disease be ascertained sufficiently soon, the treatment is simple and successful. What symptoms then characterise it? On looking at an affected eye, a peculiar arrangement of red vessels is observable. Towards the circumference of the globe they become distinctly visible, running forward in lines without lateral communications; as they approach the *cornea*, a free anastomosis takes place, and a plexus is formed a little external to the *cornea*, of a pretty deep colour in general. This is a diagnostic mark of importance. The vessels being covered by the *conjunctiva* exhibit a purplish tinge, and the lustre or clearness of the *cornea* will be diminished. But these signs of course vary in intensity. If the inflammation be acute, these marks are very apparent, in cases of an opposite nature they are nearly imperceptible. When the inflammation is violent and the red zone marked, on close inspection a greyish line will be observable, which has been called the ash-coloured zone. It is most distinct towards the *cornea*.

These characters will vary either from the degree of the inflammatory action, or from inflammation co-existing, or arising in the *conjunctiva* or *sclerotica*, or deeper tissues of the eye. The general appearance will point out in which texture the complication exists, although when high action is going on, the distinguishing features are lost in the general redness. The pain is often urgent, and in cases

where syphilis has given rise to it, the patient's sufferings become aggravated towards evening; the most distressing feelings are caused by the intolerance of light; this is most severe during the first stage of an acute attack; before muddiness of the aqueous humour and dulness of the *cornea* have veiled the *retina*, it is often as great as in strumous ophthalmia. In very severe cases there will be diffuse redness; the zone and white line are not discernible; the *cornea* is opaque, with red vessels shooting over its surface; depositions of lymph take place between its *laminae* and the patient's sufferings are commensurate. Such an attack ends in disorganisation. A train of symptoms similar to those now detailed should lead us to investigate the appearance of the *iris*, however slight these indications or the person's sufferings may be. It is by examining the appearance and condition of the *iris* that we can alone judge of the absence or presence of this disease. The practitioner should acquire a familiarity with the diversified aspect of the *iris*. He ought to be conversant with its contractions, the extent, rapidity, and duration of these under different degrees of light. Without a knowledge of these he will be often baffled in forming a decision, and will act from erroneous and detrimental conclusions.—*Ed. Med. and Surg. Journ.*

(To be continued.)

CASE OF EXTIRPATION OF THE EYE-BALL.

BY J. H. WISHART, F.R.S.E.

EURETTA DOUGLAS, ætat. 13. The right eye projects considerably beyond the orbit; the upper eye-lid is very much elongated, so as still to cover the eye when she is asleep. On her looking downwards with the eye, a firm tumour can be distinctly felt near the situation of the lachrymal gland, and extending inwards and backwards towards the bottom of the orbit. About two years ago the eye

began to increase in size without any previous pain, and without any evident cause that could be assigned. In twelve months it attained its present size, in which state it has remained for the last year without any visible change.

In the first three months nothing was done for it; but there soon occurred such a rapid increase of size, that the surgeon who was consulted pronounced it dropsy of the eye. He applied leeches over the eyebrow, and blisters to the temple, without producing any mitigation of the symptoms. She also got various medicines internally, in the form of pills, powders, &c., but without any benefit.

At a consultation it was agreed that nothing could be done to save the eye, and the total extirpation of the organ was therefore thought proper, the patient herself being most anxious to submit to whatever was thought advisable. I removed the eye on the 1st March.

The operation was performed in the usual way, and the whole contents of the orbit removed. The hæmorrhage was considerable; but the orbit being filled up with strips of fine lint, a common compress, formed of two or three folds of linen, was laid over the eyelids, and a few turns of a roller over all; the patient was put to bed, and soon after took an opiate.

On examining the eye after its removal, the disease was found to be seated in the substance of the optic nerve; the coat of the nerve being very much distended, and evidently forming the outer covering of the tumour. The eye itself was found perfectly sound and of the natural size; the previous enlarged appearance being caused entirely by the pressure of the tumour from behind. The tumour was of a firm consistence, resembling the cerebral substance, generally considered of a malignant nature.

On the fifth day after the operation the compress was removed and

gave considerable relief; no discharge followed. A small portion of the slips of lint was removed daily from the orbit. The whole was taken away in three days, very little matter being discharged along with the dressing.

From this time the patient went on without any unfavourable symptoms. She was dressed regularly twice daily, the discharge being very moderate in quantity. A small slip of lint was introduced at every dressing between the eye-lids, and a pledget of the same, spread with simple ointment, laid over all.

On the fourteenth day from the operation, the discharge was very moderate, and quite healthy; a small quantity of thick matter was seen adhering around the bottom of the orbit. A weak solution of the acetate of zinc was thrown in with a syringe, and continued every day regularly, the discharge gradually diminishing. She went out daily to walk, and before the end of the month was perfectly well. The upper eye-lid returned to its natural size, and she returned home about the middle of April perfectly recovered.

The case had a much more favourable termination than that of many others which I had extirpated from similar situations. I have never met with any cases of the same description as this one in the works of surgery or morbid anatomy which I have consulted. The only one resembling it is related by Panizza, in his work *Sul Fungo Midollare*, in a little girl six years of age, in which there was found, on dissection, not only a small tumour surrounding each optic nerve, but a still larger cerebral mass in the basis of the brain.—*Edin. Med. and Surg. Journ.*

TURKISH MEDICINE AND SURGERY.

Pedlar Physicians.—Jewish physicians abound in Turkey, and are not a whit better informed than the Albanians. They wander about the

country with their apothecary's shop on their back, and are, in fact, perfect medical pedlars. Their traffic is not confined to the sale of medicines alone. The poorest of them carry wallets and walk the streets and bazaars, at every place uttering the shrill cry of "ei Hekim! ei Hekim!" (*a physician, a physician*). Now and then you may see them stopped in the street by some unhealthy looking Turk, whose pulse they feel, and instantly roar out, "bilirim seuin hastalik," (I know thy disease,) and without asking the patient a single question, they open their wallets, give him a pill or a powder, which he swallows on the spot, after bestowing on the physician two or three half-farthings (*paras*) for his advice and medicine.

Diagnosis of the pulse.—Nothing so enhances in the eyes of a Turk the value of a physician, as his being able to tell every thing after feeling the pulse. By the pulse alone he must know not merely the nature of the disease, but must be able to say whether the patient slept well during the night before, what he ate during the day, whether the bowels are open, &c. &c. After having once felt the pulse, the physician must put no question to his patient, for it is considered as a sign of ignorance; at his very first visit he must declare, from the pulse, at what precise time the patient will die or recover.—*Dub. Med. and Surg. Journ.*

DR. YATES'S ADDRESS.

DR. YATES has published a most inconsistent address to the profession defending his conduct in acting contrary to the feelings of the profession by attending the General Dispensary, Aldersgate-street. The late medical officers have this day (Thursday) replied in the Times, and with sarcasm and irony analysed Dr. Yates' epistle and motives. They state, "we left the institution, rather than countenance a system which must lead to

the election of ill-educated or otherwise improper persons, to appointments, which should be filled from professional competency alone." They advise Dr. Yates to retire, and at the same time to disavow "that he and others are acting on an understanding with certain members of the committee, who, for want of other candidates, will recommend the Governors to recommend him and them on the 18th inst., to fill those appointments which we upon principle thought right to vacate." Signed by the late medical officers.

Dr. Yates must perceive, by this time, that he has placed himself in an awkward predicament, from which he cannot extricate himself with much credit.

MEETING TO PLACE A MARBLE BUST OF THE LATE JOSHUA BROOKES, ESQ. F.R.S. IN ST. JAMES'S CHURCH, PICCADILLY.

A MEETING of the Profession is to be held in the Museum, Blenheim-street, Oxford-street, on Thursday the 10th of October, at eleven o'clock A.M., the object of which is, to erect a bust of the late Joshua Brookes, Esq. in St. James's Church, Piccadilly. An opportunity is afforded to the Profession to prove their estimation of the high character of the late celebrated anatomists.

A CASE OF GREAT DISTRESS.

THE widow and eleven children of the late Mr. Luff, surgeon, of Bethnal Green Road, are in a destitute condition. Mr. Luff lost his life by his exertion in the treatment of epidemic cholera among the poor, and his family have just claims upon his professional brethren.

**A TRANSLATION OF BARON ALIBERT
ON DISEASES OF THE SKIN.**

BY SAMUEL PLUMBE, M.R.C.S.

(Continued from page 243.)

**FACTS RELATIVE TO THE GENERAL HISTORY
OF SCALD HEADS.**

THE phenomena we are now going to present our readers are such as are common to the different kinds of teigne.

ARTICLE I.

Of the general appearances which characterise the course of scald head.

The individuals, in general, who are attacked with any kind of teigne whatever, feel an itching more or less violent on the head. The scalp, in certain parts of its surface, becomes red, cracks, or often even swells. Sometimes the glands, whether cervical or occipital, swell, and are painful to the touch; sometimes, also, but more rarely, a severe headach accompanies this cutaneous affection. The itching increases daily. You then perceive, between the hairs and on the scratched parts, pustules or vesicles, surrounded with an inflamed areola. In some cases there are no traces of ulceration; you see small dilated canals, or the pipes of several glandulous follicles, from which a viscous and red humour flows slowly. It may happen, especially in the mucous scald head, that the skin rises in circumscribed tumours, tolerably hard at the basis, having the top soft and whitish, and containing a yellow fluid. This fluid issues with foetidity whether you give it vent with an instrument or allow it to suppurate and rupture, applying only poultices. The hairs are very soon bathed with this impure matter, which agglutinates them to each other, and coagulates in the air and heat. The flakes of this viscous humour, which flows abundantly, accumulate and form crusty or squamous layers, which unite and produce a horrible and hideous covering for the

head; but under this covering is a putrid sanies which attacks the skin frets the hair even to the bulb, consumes the neighbouring mucous structure, and threatens even the bony substance of the skull. Some patients are a prey to dreadful nocturnal pains; others become so dreadfully thin as to arrest their growth. When the teigne has existed from infancy, or that suitable means have been neglected for the cure, its ravages are particularly great. It is then you see abscesses form in the scalp, and glandular swellings in the occiput, neck, shoulders, and arm-pits. The ears sometimes inflame and tumefy in a dreadful manner; the pustules emit a repulsive odour, and become confluent; the old hairs fall off, and those which replace them are white, soft, and grow slowly; their tufts are clear and fine, resembling a lanuginous substance. The mind is not fit for any intellectual work, or the body for any physical exercise; in short, I have seen this dreadful disease attack the most precious sources of human preservation, and retard for a long time the organic development of the signs of puberty. I observed this particularly in the case of a young man, aged 21, by trade a joiner, who showed no signs of manhood; his voice is clear, and resembles that of a child of twelve years old; his figure bears almost the same disproportion. He was born with the favous scald head, and his father was afflicted with it. It is a remarkable circumstance, that two girls, the one twenty and the other sixteen, exhibited identical symptoms; both appeared to be only ten years of age, and were in a deplorable state of leanness. There were several favous patches in different parts of the body, and the cervical glands were enlarged. This affection had developed itself almost immediately after their birth.

The teignes co-exist sometimes with other alterations, which manifest themselves in other parts besides the scalp. That which particularly deserves the attention of pathologists is the deformity in the nails, which sometimes

happens to individuals afflicted with the *T. faveuse*, especially when this disease continues long after puberty. A case is recorded by Murray of a young girl afflicted with a remarkable deformity and discoloration of the nail of the little finger on the left hand. On cutting this nail with a knife there flowed a glutinous humour similar to that which escaped from her head. Several authors have noticed this singular phenomenon, which appears to bear some analogy with the *plica*; and this is not the sole resemblance between them, as I shall have occasion to show by and by. The resemblance is strong enough to bring them naturally near each other in nosological arrangements.

The several teignes we have described rarely attack children during lactation. I have, however, excepted the mucous scald head. It is clear that the greater number of individuals who have this affection have reached their second year, and that it lasts for the first seven. It sometimes extends beyond this, but very rarely. It happens, nevertheless, that some of the forms show themselves in advanced age, principally the *T. faveuse*. The amianthous teigne only attacks adults. To be convinced of this, it is only necessary to consult the cases we have collected. The teignes are not like other eruptions which perpetuate themselves in the animal economy, and which, when neglected, never disappear spontaneously.

Nature, which promotes these exanthemas for ends not yet perfectly known, usually causes them to disappear at the age of puberty, and often before that period, without the assistance of art. I have already said that the appearance of the teignes was accompanied with the obstruction of certain glands. It is not certain whether these obstructions are the causes or effects of these cutaneous eruptions, or if they are only concomitant symptoms, as they sometimes precede, sometimes follow, their development. The glandulous tumefaction is often so connected with them,

that it disappears when you succeed in curing them. We must not confound this tumefaction with the scrofulous or venereal obstruction; these are cured by quite different means. I have often tried to determine, at the Hospital St. Louis, the relative number of the different kind of teigne; and M. Gallot has frequently assisted me in the calculation. The favous form presented itself most frequently to our notice: out of a hundred individuals submitted to our examination ninety were affected with it;—the granulated, one in ten. We have still more rarely met with the furfuraceous. This may arise from the patient's not coming to the hospital for advice, this species being less troublesome and alarming than the preceding ones. The amianthous is most rare, and that appears to me the reason why no author has, to this day, described it. As to the mucous form, great towns abound with it; but as it generally arises during the period of suckling, or the first two years of infancy, children afflicted with it are rarely separated from their mothers or nurses.

CASES TREATED IN THE STIRLING DISPENSARY, WITH REMARKS.

BY W. H. FORREST, SURGEON.

Meningitis of the Spinal Chord.—Alexander Jaffray, æt. 26, was admitted on the 19th May, 1831. He had complained for a week before of pain in the back and legs, which was mistaken for rheumatism. When I saw him the pain was exceedingly severe over the whole body, but especially in the back. He had, too, tetanic contractions of the muscles of the back, neck, legs, and arms, amounting to perfect opisthotonos. His pulse was 150, small, and very sharp; his skin was hot; his urine was scanty; and his bowels were constipated. The intellectual functions were entire. During the first two days of my attendance I bled him very copiously, and gave him drastic purgatives in large doses. On the evening of the 20th, a blister, extending from the

occipt to the sacrum, was applied. On the 21st he took more purgative medicine, and a pill, composed of two grains of calomel and three of opium, every two hours. On the 22nd, the pain and tetanic contraction still continuing, I dressed the blistered surface with tartar emetic ointment, and continued the calomel and opium. On the 23rd and 24th he took more purgative medicine, and the calomel and opium and tartar emetic dressing were continued. On the 25th the pain and tetanic contraction had completely subsided, but he complained of the blistered surface, which was highly inflamed; I ordered a dose of castor oil, a linseed poultice to the blistered surface, and the calomel and opium to be withdrawn. On the 26th he was still free of pain and spasms, but complained very much of the blistered surface. On the 28th his strength, which had hitherto been pretty good, gave way to a considerable extent. His pulse was very frequent and weak, and there was a good deal of low muttering delirium; a portion of the blistered surface had sloughed. I ordered him a solution of quinine, with sulphuric acid, and a wash of chloride of lime for the back. 29th. Sloughing going on rapidly; quinine and chloride of lime continued. 30th. A very large slough, comprising the cutis merely, was removed. In the evening he felt much better; the delirium had completely subsided, and his pulse was less frequent and fallen. 31st. There was a slight return of the pain and spasms, and his pulse became again frequent and sharp. A consultation was held, and it was determined to put him under the influence of mercury. He took accordingly calomel combined with Dover's powders, and had the blistered surface dressed with mercurial ointment. The pain and spasms continued in a slight degree for two days, when they yielded entirely to the mercury. He was discharged on the 16th June perfectly recovered.

This was an example of meningitis

or acute inflammation of the membranes of the spinal chord, a very rare disease. Dr. Abercrombie, notwithstanding all his experience, does not appear to have seen a case during the lifetime of the patient. It will, I believe, be generally found, that in pure meningitis of the chord tetanic contraction is present. Dr. Abercrombie alludes to several cases of this affection complicated with meningitis of the brain, in all of which pain extending along the spine, and tetanic contraction of the muscles of the back and neck, were the prominent symptoms. Severe pain in the back, shooting into the extremities, chest, or abdomen, and attended by tetanic contraction of the muscles, and long fever, appear to me to express, very correctly, the principal external characters of this affection. The treatment of meningitis of the chord is sufficiently obvious. I am disposed to place great confidence in powerful counter-irritants; and I believe it was the severe action of the tartrate of antimony which saved my patient. The disease showed no disposition to yield until the pain of the blistered surface became more intolerable than that of the disease, and as soon as the severity of the action of the tartrate had subsided, the spinal pain and tetanic contraction returned, and continued until they were finally removed by the mercury.

Abscess of the Liver bursting into the right cavity of the Chest.—John Webb, æt. 35, had complained for a month before of pain in the region of the liver, and of great prostration of strength. When I saw him he was very much emaciated, and looked like a person dying of abdominal organic disease. His skin was of a pale lemon colour, and his countenance was very anxious and ghastly. He still complained of pain in the site of the liver, but there was little if any tenderness, and no fluctuation, in it. He ascribed the pain to rheumatism. His pulse was 120, small and feeble; his tongue was pretty clean and reddish;

his bowels were painful and irritable, but not loose; and his breathing, though a very little hurried, appeared to be fully and freely performed; he had no cough, no difficulty in breathing, and in short no symptom which indicated in the most remote degree, the existence of thoracic disease. He generally lay on his back, but stated that he could lie on either side without inconvenience. The case altogether was very obscure, and as the man, whatever might be the nature of the disease, appeared to be dying, I resolved to support his strength merely, and to palliate any urgent symptoms that might arise. On the 14th he was seized with diarrhoea; his stools were foeculent, but they had a peculiar and very disagreeable odour which I cannot well describe. The diarrhoea was easily checked by the chalk mixture and opiates. On the 8th of March it returned with increased violence, and demanded a further use of chalk mixture, opiates, and kino. It was in a great measure subdued by these remedies, but the bowels continued painful and irritable to the last. He died on the 14th of March at half-past 8 A.M.

Dissection.—The whole body was very much emaciated. In the upper part of the right lobe of the liver, there was an abscess about the size of a small fist, filled with a thinnish pus of a rose-red colour. This portion of the liver adhered very firmly to the diaphragm, but the rest of it was quite free and healthy. The gall-bladder was healthy and full of bile. In the right side of the thorax, there were six pounds, as nearly as could be computed, of the same rose-red pus, found in the liver. The right lung was compressed to a mere membrane, four inches and a half in length, two and a half in breadth, and a fourth of an inch in thickness. The pleura was thickened and blanched, but there was no deposit of false membrane on it. The left side of the chest was quite healthy. Betwixt the abscess in the liver and the right side of the thorax there was an opening through the

diaphragm, an inch in diameter. There was nothing unusual in the bowels or other organs.

This case is remarkable for the quantity of purulent matter contained in the right side of the chest, rendering the whole of the corresponding lung entirely useless, yet giving rise to no symptoms which led even to a suspicion of disease in this situation; from which circumstance may be gathered the necessity in every supposed case of abscess in the liver, of examining the right side of the chest, even although the symptoms do not indicate the existence of disease in this cavity, as well as the possibility of one lung maintaining, in certain circumstances, the respiratory function to an extent sufficient for the purposes of the system.

(To be continued.)

ON THE PATHOLOGY OF UTERINE DISEASES.

BY PHILO.

EVERY practitioner of candour will acknowledge that he has often been puzzled how to account for, as well as how to treat, that distressing state of the system, which is produced by any irregularities in the catamenial discharge. I will not stop to inquire whether the diseases termed by nosologists, amenorrhœa, chlorosis, hysteria, &c. are distinct in their pathology, or are merely degrees or modifications of the same complaint. To me it has always appeared that the theories of systematic writers are very unsatisfactory on this subject, and that they have taken a false view of the nature of these disorders.

The first glance at the patient might lead any person to suppose that she is suffering from extensive disease in some organ of vital importance. She crawls across the room as if a heavy weight were attached to her feet, and she sinks, apparently exhausted, into the nearest seat. The heart flutters, imitating all the *bruits* of the stethoscope; the pulse bounds

under the touch; there is pain of extreme violence, chiefly of the head, back, or epigastrium. It is not my intention on the present occasion to enter upon an extended inquiry into the pathology of these disorders, but I shall content myself with making a slight review of the opinions on this point, which are most in fashion, and afterwards seeing whether or not these notions of the disease are adequate to account for such a remarkable train of symptoms.

There can be no question that suppression of the menstrual flux depends in very many cases upon disorders in the uterus or its appendages; but it is obvious that a vast degree of constitutional disturbance is set up, when there is not any considerable departure from the healthy action or structure of these organs, for we frequently observe cases of suppression where the functions of the uterus are restored without the employment of any active means. On the other hand, the womb may be diseased to the greatest extent, which may go on even to a fatal termination, and yet the patient may never have been troubled with hysterical affections.

Many pathologists look for the origin of this disease in the cerebellum, and it is certain that pain over this organ is a frequent symptom in such cases. But although it is frequent, it is by no means constant; and after a pretty full investigation into this subject, I find that the pain is quite as often referred to the forehead or across the eyes. I am far from denying, however, that an important connexion exists between the cerebellum and the genital organs, but on the other hand, it must be allowed that the former may be the seat of extensive disease, whilst no disorder manifests itself in the functions of the latter, and that even in the most distressing cases of uterine disease, the cerebellum is not necessarily affected.

A very important step towards the successful investigation of the sub-

ject, is the fact, that hysterical symptoms, similar to those above enumerated, rarely occur, except during that period of female life when the uterus is capable of performing the function of menstruation, which in this country includes the period between the ages of seventeen and forty-five. In addition to the above fact, and probably depending upon the same cause, women who have never menstruated from a want of development in the uterine system, are seldom hysterical. I lately saw a young woman, aged twenty-seven, in whom this secretion has never appeared, the breasts remain flat as in childhood, but she has no hysteria. As illustrating this subject, it may be mentioned, that in cases where the uterus has been totally extirpated, and where the catamenia have consequently been suspended, the patients have usually become plump and healthy. Also, in the progress of debilitating diseases, of phthisis more especially, there is most commonly a suspension of the secretion, arising from an exhaustion of the circulating fluid, but this occurs without any hysterical symptoms.

Taking into consideration these circumstances, it seems obvious, that to produce the distressing agitation called hysterical, either the catamenia must be secreted, or at least that the uterus retains the power of effecting the secretion.

What is it, then, which excites such a wonderful commotion in the system. Is it merely that a plethoric state is induced? In many cases one look at our patient will satisfy us that her disease does not arise from a redundancy of blood.

It has occurred to me that all the symptoms can be satisfactorily accounted for if we suppose that the menstrual fluid after having been secreted, is again carried into the circulation by means of the absorbents or otherwise. In the practice of medicine we meet with similar processes, causing very remarkable and

extremely distressing results, such as the absorption of the urine, or piles, for example. To my mind, at least, the explanation now advanced appears more accordant with the phenomena of the disease than any other that I am acquainted with. The sudden depression, the labouring heart, the severe pain, the altered colour of the skin, and the dyspeptic symptoms, are what might *a priori* be expected from such an exciting cause. If any of your correspondents will bring forward facts to elucidate or overthrow this opinion, I shall be equally gratified, and therefore request you will insert the above sketch in your most valuable publication.

September 11th, 1833.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, September 30th, 1833.

WILLIAM KINGDON, ESQ. President,
in the Chair.

Commencement of the Session for 1833-34.—President's Address.—

History of Cholera at Jessore.—

Deteriorated Rice the cause of the disease in that and every other country.

THE President delivered an eloquent address, in which he congratulated the meeting, which was extremely crowded, upon the prosperous condition of the Society, and stated, that he had the assurances of several able and experienced members of their zealous co-operation for the support of the institution. He hoped and trusted that the debates would be interesting and valuable; and he felt convinced from the presence of those he saw around him, the experience of most of whom had been very extensive, that the results of their observations would afford a mass of the most valuable information, scientific as well as practical. He was satisfied that the Medical Society of London would continue to obtain that support which

had long been given to it by its old and valued members; while he anticipated a proportionate degree of zeal for its interests from those who had more recently joined it.

Thanks were then voted to the different officers. The minutes of the last meeting were read and confirmed.

The President then announced to the Society, that there was a gentleman who favoured them with his company as a visiter this evening, from whom they would learn many interesting facts and experiments.

Dr. Titler, of the East India Company's Service, then addressed the meeting, and made a communication to the following effect:—That he was the only medical practitioner who had seen the disease called cholera, at Jessore, in 1817, that the Bengal medical statement was founded upon his own, that he had unequivocally traced its origin to rice of a deteriorated quality, being of a reddish colour, which he ascribed to a covering that it possessed, which was not the husk, and that this covering was poisonous to man and animals*. He gave a description of the various kinds of rice, presented various specimens of the best and worst qualities, which he had purchased in this metropolis, and went on to prove that the rice imported into Europe and the West Indies from Bengal, which was the deteriorated crop of 1817, was the cause of the disease called epidemic cholera, yellow fever, and dysentery. He stated that the rice crop had failed in 1816 at Jessore, in consequence of which there was famine among the natives; that the crop of 1817 was the most abundant ever known, that it was cut unripe, to supply the necessities of nature, it was the food of the people, and had caused

* As to the idea of contagion, it was ridiculous. He had handled the patients, inspired their breath, slept in beds from which they were removed immediately after death, but was not affected by the disease.

vomiting and purging in two or more hours after being eaten. He discovered this by accident, as a gentleman, named Watts, had written to him that his servants were seized with the epidemic, which then raged, in two hours after a repast of rice. He cited numerous authorities, both civil and medical, to prove that the unripe and deteriorated rice of 1817 had caused purging and vomiting; and he cited the testimony of Mr. Chapman and Dr. Duncan Campbell in support of his experiments, that rice and water affected goats with diarrhoea and dysentery. He was proceeding to prove that the rice of the crop of 1817 had caused yellow fever in the West Indies, and the late epidemic cholera in this country, when

The President rose and said, that perhaps he had committed himself in having allowed a discussion of this kind, however important, to occupy the whole evening, as several gentlemen might have been disposed to narrate cases of patients under treatment, and to solicit the advice of the members at large on such cases. Many gentlemen had appointments, and had to see patients after the usual hour of adjournment; but he was in the hands of the meeting, and wished to learn if it were the wish of the Society to hear the gentleman for a longer period.

Dr. Blicke observed, that his time was limited, and regretted that he should be obliged to leave at the usual time, as he felt great interest in many facts adduced, though as one who had been in India, he should consider that the gentleman's conclusions were wrong. He, however, should be most happy to hear the conclusion at the next meeting, and to reply to it; but circumstanced as he was, he should move an adjournment, with a request to Dr. Titler to conclude his observations at the next meeting.

Dr. Walshman complimented Dr. Titler for the many authentic facts he had mentioned, and felt assured that the Society would hear the re-

mainder of his observations with great attention at the next meeting of the Society.

We give Dr. Titler great credit for the indefatigable zeal which he evinced in investigating the disease at Jessore, which he and the Bengal Medical Board designated cholera. He did not, however, in a paper which occupied an hour, state one symptom of the late epidemic cholera which prevailed in this country, except vomiting and purging. The only thing he proved, beyond doubt, was, that blighted or deteriorated rice disordered the stomach and bowels; but certainly not that it was like spasmodic, or, as some will have it, Asiatic cholera. But, in fact, he had not an opportunity, as the hour of adjournment of the Society had arrived before he had concluded. We trust he will elucidate the remainder of his argument at the next meeting.

REFUSAL OF MEDICAL MEN TO GIVE EVIDENCE AT INQUESTS.

Two recent instances of this have occurred. Mr. Godrich, surgeon, of Chelsea, at an inquest held a short time since, refused to give his opinion as to the cause of death, unless he was remunerated for so doing, and in a more recent case still, Mr. Ross, surgeon, of Ratcliff-highway, refused to give his evidence on an inquest on a child who had been drowned, unless his expenses were paid. In the latter case, Mr. Baker, before whom the inquest was held, talked somewhat vehemently about commitment for contempt, &c. We should seriously advise Mr. Baker and his coroner colleagues to beware how they interfere with the *rights* of medical men, or they may find themselves in a very awkward predicament. Lord Melbourne, the Secretary of State, has been applied to, but his answer has, we regret to say, been unfavourable. We trust that during the next session of Parliament an act will be passed affording a remuneration to medical

practitioners attending on inquests, as has recently been done with reference to the profession in Ireland.

THE

London Medical & Surgical Journal

Saturday, October 5, 1833.

THE MEDICAL SESSION OF 1833—34.

THE greatest exertion has been made in the large and small medical schools of the metropolis during the last few days, and the most vigorous competition has been manifested by all parties. The result will be, that students will derive greater advantages than during any former session. It would be invidious in us as lecturers to give a comparative view of the different schools, or comment, as a contemporary has done, upon their respective merits. We feel convinced, that the lecturers, in almost all of them, are eminently qualified to discharge their duties. It is to be remembered, that no lecturer, but one of superior attainments, is recognised at present, and this is a sufficient guarantee to medical students. The only advice we would give to students, especially to those who have just arrived from the country, is, not to be influenced by what are called great names. They will find that the terms of the large schools are double those of the smaller ones; the instruction is as good in the latter as in the former, for almost every one of the lecturers in London has been a private teacher. There are some students who will enter to the large schools,—there are others who prefer

the smaller ones. A great mistake is made by students entering to certain lectures in different schools, by which they lose a vast deal of time, in going from one place to another. This error ought to be avoided. The whole time of those commencing the study of the science of medicine should be devoted only to that object, and not foolishly spent in amusement or dissipation. Students owe it to themselves, to their friends, and to their country, to spend their time solely in the acquirement of medical knowledge. They will have sufficient leisure for recreation in any of the schools, but every lecture of the courses prescribed by the constituted authorities in the profession, should be duly attended.

MEDICAL DEGREES GRANTED IN LONDON.

We are highly gratified to perceive, by the introductory lecture of Professor Grant at the London University, that the government is determined to grant the University the power of conferring degrees in medicine. We have repeatedly urged the expediency of this measure in our pages.

DISSENSION AT ST. BARTHOLOMEW'S HOSPITAL.

The removal of Mr. Skey from the demonstratorship at the medical school of the above hospital has given displeasure to several of the students. Mr. Stanley, on commencing his introductory lecture, was received with

marks of disapprobation mingled with applause. He stated, that any pupil, who felt dissatisfied, might have his fee returned, and that the Governors and Medical Officers had unanimously approved of the present arrangements.

THE GENERAL DISPENSARY,
ALDERSGATE STREET.

PRESS of matter prevented us last week from inserting the following communications relative to the above institution, and we now give them a place in our pages with much pleasure. Though we have animadverted with some severity upon the decision of the Committee and Governors as to vote-making and bribery at the election of medical officers, we are most ready to give that portion of their letter which they offer as a defence, omitting all their lengthened details on minor and irrelevant matters. After the most impartial consideration of the defence we think it lame and unsatisfactory, and we shall prove that the system of vote-making at medical elections is most injurious to the real object of Dispensaries, which is the relief of the sick poor, as well as to the respectability and dignity of the medical profession.

The Governors must be convinced of the validity of this conclusion by the comments of the public and medical press on their proceedings, and by the glaring fact, that no physician or surgeon of standing or respectability, with one exception,—and the individual who made the exception suddenly retired,—has ventured to accept office in the institution. The system which they and most other managers of Dispensaries adopt leads to the sacrifice of the unfortunate poor, by the appointment of inexperienced medical advisers, is uncharitable, and destroys all the advantages of sound medical knowledge. The practitioners of medicine have long deplored this evil, and have opposed it on every

occasion, but the late medical officers of the General Dispensary have given it a final and a fatal blow, which must lead to its complete removal.

To the late Medical Officers of the Aldersgate Street Dispensary, London.

Gentlemen,—At this interesting period in the state of our profession, and especially in the government of medical charities, we should be guilty of the most culpable apathy and indifference did we not hasten to express the high satisfaction with which we have viewed your conduct on a late occasion, did we not testify how completely our feelings and sentiments are in unison with your own, did we not publicly record our warmest admiration of that brilliant example of integrity and independence which you have exhibited to your medical brethren.

Whatever sacrifice of feeling or interest has been made, you have the consolatory approval of upright consciences. You have acted consistently and like honourable men. You have discharged an important duty both to medical practitioners and to society at large. You have nobly withstood a most disgraceful attempt to degrade your profession and to convert a health-giving charity into an infected source of misery and wretchedness; and whilst you enjoy the praise of every virtuous and enlightened mind, it may perhaps prove a further gratification to know that your medical brethren in particular are fully alive to the moral force of your example, that they appreciate its worth, and are resolved its memory shall not die.

Gentlemen, we hail this example, the first practical inroad on a protracted and systematic abuse of medical charities, as the harbinger of a general and efficient reform in those charities; we hail it as the forerunner of an approaching day, when the legislature shall rescue them from longer prostitution of their legitimate ends, a day when the neglected objects of science and the aims of general utility and benevolence shall happily be

united,—when not personal interest, nor gold, nor any other corrupt means whatever, shall give notoriety to the officer of an hospital or dispensary, but when talent and knowledge alone, approved by public competition, shall be the test of fitness for office in such institutions.

The folly which compelled your withdrawal from the charity you upheld foresaw not the consequences about to follow. Its sordid calculations of gain did not reckon that, with the loss of your labours and skill, the very charity you served would cease to exist. For where shall be found the men reckless enough to succeed you? The very attempt would brand their characters with all that is low, degraded, and debased.

Accept, gentlemen, this tribute of our gratitude; we deeply feel the obligation under which you have laid the whole profession. Assuredly the members of that profession will not forget a lesson so disinterested and elevated as that which you have given for their instruction, signalised, too, as it is, by names distinguished in the scientific and literary history of their country.

We remain, Gentlemen, with the greatest respect and admiration,

Corden Thompson, M.D., physician to the Sheffield General Infirmary; Wilson Overend, surgeon to the Sheffield General Infirmary; Henry Paul Harewood, M.D., physician to the Sheffield General Dispensary; John Green; George Calvert Holland, M.D., physician to the Sheffield General Infirmary; Henry Thomas, surgeon to the Sheffield Public Dispensary; George Turton; R. G. Holland; Thomas Reade; Henry Hardy; Charles Eadon; Joseph Law; Joseph Ingall; R. S. Taylor; John Carr; James Wild; G. Reddal; George William Clark; James Ray; James F. Wright; Edward Thompson; Henry Boulton, F.L.S.; Edward Gillot; W. Lennard, M.D.; Knowlton Wilson; John Hall; Samuel Gregory; John Pearce Lewis; John Foster; John Turton; Joseph

Riley; William Staniforth, senior surgeon to the Infirmary; Wright Wilson; Henry Jackson, junior surgeon to the Sheffield General Infirmary; James Walker; R. Ernest, M.D., house-surgeon to the Sheffield General Infirmary; John Pearson Shaw; W. Favell; John Haxworth, surgeon; William Jackson; Francis Pearson.

Sheffield, Sept. 22.

To Dr. Corden Thomson and the other members of the Medical Profession in Sheffield.

GENTLEMEN,—We have received, with the most heartfelt satisfaction, the eloquent testimony of your approval of our conduct in the step which has terminated our connexion with the General Dispensary. In making a sacrifice of feeling and interest to the respectability of the profession, and the welfare of the sufferers which it is the object of the profession to relieve, we reckoned on the sympathy and support of medical men, and we have not been disappointed. Many and cheering are the proofs which have been afforded to us of this sympathy and support, but none more honourable or gratifying than that which we have received from you.

We cannot but hope that under such encouragement, through the establishment of the principle for which we have been contending, we may contribute to the permanent welfare of all medical charities, as well as to the honour and respectability of our profession.

We are, gentlemen, with sentiments of gratitude and esteem,

Your very faithful servants,

George Birkbeck Julius C. Roberts
H. Clutterbuck Frederick Salmon
William Lambe William Coulson.

London, Sept. 27th.

A Letter from the Committee to the Governors of the General Dispensary, Aldersgate-street, on the resignation of the Medical Officers.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—The Committee of the General Dispensary, Aldersgate-

street, beg leave to forward the Editors a copy of their Address to the Governors of the Charity, with a conviction that they will give so much of it a place in the valuable columns of their Journal, as will put the question between them and their late medical officers fairly before their readers.

*Dispensary House,
Aldersgate-street,
Sept. 27th.*

The following extracts from the Address of the Committee contain the defence of that body to the charge of the medical officers.

"The Committee became convinced of the necessity of an alteration being made in the privilege of voting, their attention being called to the comparatively small increase of subscribers in the years 1828, 1829, 1830, and 1831, as compared with previous years.

The Committee further observe, "that upon the vacancies being declared, gentlemen who were desirous of offering themselves as candidates were deterred under this *now* favourite law from canvassing the governors, stating that they found, upon the beginning of their canvass, that the votes of the Governors had been so far secured, previously to the vacancy being declared, that left others no chance of success."

This statement is literally true; but it applies to every dispensary in the kingdom. When a medical officer is about to retire he apprises some friend whom he wishes to succeed him, a private canvass is set on foot, the subscribers or governors have the interests of the poor so much at heart, that they promise their votes to some acquaintance; and when an advertisement appears in the newspapers, candidates announce themselves, commence a canvass, and find that all votes have been promised six or twelve months before the vacancy was declared. This system of humbug is practised in most dispensaries, and is no novelty in the General Dispensary, Aldersgate-street.

With these facts before them, the Committee considered, that "without some alteration in the system, the election of medical officers to the Institution was becoming a mere farce—that the medical appointments were daily approaching to a period when they would be claimed as the vested rights of those in power to appoint whom they should think proper to be their successors. It was to break down this growing monopoly, and to give to every respectable and talented medical practitioner a like opportunity of being a candidate, with an equal chance of success, and to instil new life and vigour into the Institution, that the Committee came to the resolution of recommending to the Governors an alteration of the law for the future election of its officers—an alteration that will continue to prevent the making of *proxy voters upon the eve of an election*, which was not the case when Drs. Birkbeck, Clutterbuck, and Lambie were elected, any person being at that time, and for several years afterwards, allowed to vote either by proxy or otherwise, provided the subscription had been paid *only four days before the election*. In Jan. 1825, this law was altered, declaring that no annual subscriber should from henceforth *be allowed to vote who had become a subscriber within six months before an election*; and it was at the last general meeting again altered, by reducing this period for new subscribers to vote by proxy, from six months to two, allowing, however, any person to attend and vote personally, who should become a governor *seven days before the election*. But, to prevent any improper use of the proxy votes, all elections must take place, and the vacancies be filled up, *within six weeks* after such vacancies have occurred. And it is upon the latter alteration, carried by the votes of 86 Governors against 47, leaving a majority of 39, that the medical officers have grounded their complaints against the Institution."

Here the cloven foot appears, for the Committee could make no money

by proxy votes; but new governors of seven days' standing were a profitable speculation. The candidate could not procure proxy votes, but he or some friend might come down to the treasurer seven days before the election and buy himself into the Institution. Well might the medical officers ground their complaint upon such a venal system as this.

We must illustrate this trafficking in public characters by a few recent examples. A short time since there was a contested election for the office of surgeon to the Bloomsbury Dispensary. Professor Cooper, of the London University, a gentleman who has done much for the fame of British surgery, by works that are known all over the world, was a candidate on that occasion. There could be no second opinion among the profession, but that he was infinitely better qualified from the proofs afforded by his standard productions, by his great experience in the army during the late war, by his appointments as surgeon to the King's Bench and Fleet prisons, and by a most extensive private practice, to the juniors who opposed him. One of these, who had just passed the Royal College of Surgeons, threatened to make 600 to 1000 voters to carry his election. His father, who was wealthy, thought this a good way to invest his money, and advance his son in life, but on cooler reflection he saw the job was so gross, that he abandoned it. Here is a case for the consideration of the Governors of the General Dispensary. But we shall give them another or two. To their eternal credit the Governors of St. Bartholomew's Hospital, who are quoted as paragons of perfection by their Aldersgate-street brethren, they preferred a junior by many years to Mr. Cooper as assistant-surgeon to that institution. The last instance of corruption and abuse in a public charity which we shall notice, was one so flagrant, that we cannot help adducing it, though, as it affected ourselves, we should much rather have

passed it over in silence; did it not prove such an excellent case in point. This occurred in the Royal Maternity Charity, on a late vacancy for the office of physician. The majority of the Committee of that institution were, like their brethren of Aldersgate-street, opposed to the medical officers. The physicians to the Charity unanimously signed a declaration, that the Editor of this Journal "was incomparably better qualified than either of the other candidates who had offered themselves," though one of these gentlemen was the personal friend of two of the physicians. Nevertheless, the committee, with some exceptions, censured the physicians for the expression of their opinion; one of them insulted one of the medical officers in the strongest terms, and, aided by a party, favoured the pretensions of the candidate considered, by those capable of judging, the least qualified for the situation.

When the testimonials, consisting of medical degrees, diplomas, and documents from the most eminent physicians and surgeons in these kingdoms, in France, and in America, were presented to the Committee on the part of one candidate, a clerk in the Bank stood forward as judge, and his party, who were the most numerous in the Committee, refused to comply with the proposal of the Chairman, that one of the medical officers, who were present, should inform the Committee of the respective claims of the candidates. But this self-constituted censor of medical degrees and testimonials, declared both candidates equally eligible, as one had an Edinburgh degree, the other a Glasgow one; and as to the licence of the Colleges of Physicians and Surgeons of London, and the other documents, they were nonsense! The next step was, that the favoured candidate went to the Secretary at the eleventh, indeed nearer to the twelfth hour, and made fifty proxy votes, which turned the scale in his favour.

We put it to the common sense of the Governors of the Aldersgate-street

Dispensary, whether the above system which they have adopted, of allowing subscribers of seven days' standing to vote at medical elections, is not opening a door to persons to buy themselves into situations, however inferior in talent to others. Well might such men as the late physicians and surgeons of the General Dispensary feel indignant on being associated with incompetent colleagues, the depth of whose purses, and not their scientific attainments, was a passport to place. Well might Dr. Roberts quote the passage—

"When vice prevails, and impious men bear sway,
The post of honour is a private station."

But the Governors assign another reason for the conduct of the medical officers, with what justice we cannot pretend to state.

"We might, however, assign another reason for their bitterness; which is, that at the time the above alteration was made, a regulation was also added, as an additional security to candidates, declaring '*every person to be incompetent to be a candidate, who, either directly or indirectly, shall solicit, or authorise, or permit any person to solicit the vote of any Governor in his favour previously to the notification of the vacancy by public advertisement*;' and to prevent the fears expressed by the medical officers being realised, that under the new regulations incompetent persons might be elected by the weight of their purse, a rule was introduced by the Committee, and passed into a law by the Governors, '*That no person shall be eligible as a candidate for any medical office whose testimonials shall not have been previously approved of by the medical committee*.' So that if any incompetent person should, by any chance, succeed in getting himself elected, he could only do so by neglect of duty on the part of the medical committee, in reporting a candidate eligible, who, by the laws of the charity, is declared to be ineligible."

We highly approve of both these laws, and feel convinced that the late medical officers entertained a similar feeling, but the value of both regulations was destroyed by a vote-making rule, for any candidate, who was admitted by the medical committee, and did not canvas before the declaration of the vacancy in the newspapers, might make as many Governors as he pleased seven days before the election, and secure his return. We cannot believe that the Governors are so short sighted, or bird-witted, as not to perceive the force and justice of our conclusions. They may rest assured, that the public sees clearly the tendency of their policy. They ought also to remember that the legislature, during the last session, put an end to vote-making and bribery at medical elections in Ireland, and that there is every reason to believe that a similar act will be passed next session of parliament for this section of the empire. We have long exposed the abuses in dispensaries and hospitals in this part of the kingdom, and submitted our exposures to the most influential members of the legislature. We feel convinced, that the time is at hand when the hideous abuses under notice will be corrected; and we offer our warmest thanks to the late medical officers of the Aldersgate-street Dispensary for their manly and disinterested conduct, in facilitating such an auspicious event. We re-call upon the profession in the metropolis and throughout the country to imitate the conduct of the medical officers of the Sheffield Infirmary, and to award well-merited applause to the humane and independent medical officers, whose noble resolution gave rise to these remarks. Their conduct will lead to the most beneficial results in hospital and dispensary elections, for certain are we that the legislature, whose eyes are now opened, will prevent such venality as would lead to the butchery of the poor and miserable.

CHOLERA IN SPAIN.

CHOLERA rages extensively in some of the finest provinces in Spain. At Seville, the deaths amount to 113 a-day. Its ravages are confined principally to the poorer classes, of whom a daily paper makes the following statement:—

"As the disease broke out among them, all communications with their district was interrupted. Abandoned as they were, in a manner, to fate, not having the help of any physicians, nor even a hospital, in their despair they attempted to take refuge, *en masse*, in Seville. They were repulsed by the bayonets of the troops; and being further threatened by the grape-shot of the cannon pointed against them, they have been compelled to remain in the abode of infection. The only favour granted them, was the sending a few physicians to them; but even these were unwilling to trust themselves to that part of the town, and therefore were taken there by actual compulsion, and under the escort of soldiers. The sanitary laws and regulations in this country are more remarkable for the barbarism than the prudence which suggested them. If they are acted upon, as has hitherto been the case, nothing will prevent the cholera from travelling all over Spain, and much mischief besides will occur. Communications are already interrupted in many parts of Andalusia and Estramadura, and all commercial intercourse is there suspended. The towns are surrounded with military cordons, beyond which no one is allowed to go or come."

Here we have presented to us a dreadful picture of the results of the "contagion" doctrine. The most besotted ignorance and the blindest folly are here mixed together, and the death of thousands will be the result. Our friends in Whitehall-place will doubtless laugh in their sleeves, and, like the fool with his cap and bells, grin at the mischief they cannot comprehend. The authorities in Seville

and in London are pretty nearly on a par; common sense is as great a stranger to the one as the other.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Abscess of the Liver.—Deborah Clarke, ætat. 60, and of unhealthy appearance, was admitted on the 26th September, with a swelling situated over the region of the liver, which came on spontaneously about four months ago, and has lately occasioned her considerable pain and uneasiness. On the day of her admission, Mr. Stanley opened the tumour, and four pints of pus mixed with hydatids were discharged. Her bowels were kept well opened with oleum ricini, haustus sennæ, &c., and on the 28th the abscess discharged about four pints more of a similar fluid to that which had been before let out. She complained of great thirst. Purgatives were again administered, and saline draughts were also ordered. The alvine evacuations have been very fœtid and liquid. She feels easier and more comfortable than on her admission, and complains of no particular pain. Poultices have been applied to the abscess. Mr. Stanley said that there was no doubt of the abscess, being connected with the liver; the discharge as it occurred in this case was not common. Mr. S. expressed strong hopes of the patient's recovery.

ST. GEORGE'S HOSPITAL.

Disunited fracture of the Bones of the Leg.—A healthy man, æt. 31, a coachmaker by trade, was admitted into the hospital on the 25th of September with oblique fracture of the tibia and fibula. About fifteen weeks before his admission he was thrown from a carriage, and his heel came in violent contact with the ground, by which the tibia and fibula were fractured. The leg was then placed on a pillow, and splints applied on both

sides of the limb. He remained in this position eight weeks, at the end of which time he endeavoured to raise his leg but could not. He then went into the country, used crutches, enjoyed most excellent health, but still the fracture did not unite. On his return to town he applied for admission into St. George's Hospital, fifteen weeks after the accident. On examination, the lower portion of the bones of the leg was found to project beyond the upper; there was no shortening; and the patient complained of no pain. All the ordinary means of producing union having failed, he has been placed under Mr. Amesbury's plan of treatment, namely, to keep the fractured extremities of the bones firmly pressed against each other, and thus excite inflammation, which, in all probability, will be attended with union.

Mr. Brodie made the following clinical remarks on the case.

"In considering how we may give this man a good limb, we should reflect how fractures unite in ordinary cases, and secondly, how, in some cases, fractures do not unite. Hunter thought when a bone was broken that blood was extravasated, and that a coagulum formed on the extremities of the bone by which union was produced. Now, I think this decidedly too simple an explanation. In some experiments which I made on animals, I broke the leg of one, and examined the fracture at different periods after the injury. In the union of fractures three processes must necessarily take place; first, thickening of the surrounding substance, secondly, ossification of the callus, and thirdly, absorption of the callus.

"Fractures do *not* unite for several reasons. 1st, On account of some anatomical peculiarity of structure; 2ndly, pieces of muscle sometimes get between the fractured extremities of the bone, and so prevent union; 3rdly, if the limb be not kept in a quiet steady position after the accident union is retarded; 4thly, the state of the constitution is often the

cause of preventing union. I recollect a case of a gentleman who was growing very fat and wished to remain thin, and starved himself to prevent his growing fat; now this gentleman happened to break his arm, and union of the fracture *never* took place. I remember a similar case of a lady. Costiveness when very extreme prevents union; tight bandaging also prevents union, as the circulation is impeded, and the restorative process does not take place.

"The neck of the femur when broken does not unite with ease, indeed it is a matter of doubt whether it ever does so at all. Diseased bones when broken do not unite; I have, however, met with some exceptions to this rule. I recollect a person who had diseased clavicle, which was fractured and united. Women who have cancer of the breast are liable to have cancer in the bones. I remember an old woman who had cancer of the breast and scirrhus affection of the collar-bone; she broke the clavicle and it united.

"I have known some cases of disunited fracture in which blisters were applied with the most decided success when all other remedies have failed. Formerly a very severe operation was performed in cases of disunited fracture; Hunter had a case in which he cut down on the bone, brought on irritation, inflammation, and anchylosis. Dr. Physic, of Philadelphia, passes a seton through the fracture. This treatment succeeds very well in the upper extremities but not in the lower ones; Amesbury's plan is much better than either of these. He used to employ great pressure on the extremities of the bone, keeping them closely applied to each other, by this pressure inflammation was brought on, and union produced. I have seen this treatment succeed perfectly in this hospital. The pressure must be very great, and it always gives great pain to the patient. The cranium when fractured does not unite like other bones, neither do the bones of the spine."

The Sanctum.

The Hypochondriac Cöbler.—Seated all day on a low seat, pressing obdurate last and leather against the epigastrium, dragging reluctant thread into hard and durable stitches, or hammering heels and toes with much monotony—the cöbler's mind, regardless of the proverb, wanders into regions metaphysical, and political, and theological; and from men thus employed have sprung many founders of sects, religious reformers, gloomy politicians, "bards, sophists, statesmen," and all other "unquiet things," including a countless host of hypochondriacs. The dark and pensive aspect of shoemakers in general is matter of common observation. It is but justice to them, however, to say, that their acquisition of knowledge, and their habits of reflection are often such as to command admiration. The hypochondriacal cast of their minds is probably, in part, induced by the imperfect action of the stomach, liver, and intestines, in consequence of the position in which they usually sit at work.—*For. Quart. Rev.*

New Method of Communicating Disease—A Hint to Contagionists.—It is a fact perhaps worthy of note, that in electrifying a person, unless the medical electrician is sufficiently on his guard, a *partial transfer of the malady of the patient may be made to him*, and this we have been assured *has actually been the case* more than once in the practice of an eminent medical electrician.

Morison's Female Friend.—We have received the letter of "A Constant Reader," and we should advise him to lay a complaint before a magistrate, respecting the doings of this lady, for her unfeminine presumption in interfering with the patients of a properly qualified practitioner. If the person affected with small-pox died, most certainly might this lady be indicted for manslaughter. A letter to the Commissioners of Stamps at Somerset House, informing them that this "fair one" sells patent medicines without a licence, would certainly subject her to the most unfeminine fine of 5*l.* for each separate offence.

A New Diploma of Medicine.—A. B. C. is informed that there is no individual in London who can grant a degree of doctor of medicine or a diploma of surgery or pharmacy. The individual who acquired the few feet of parchment, which he calls a medical diploma (?), after two days' severe examination, must, we presume, have obtained it from the gentlemen who grant diplomas from the London College of Medicine.

We shall notice the letter of our correspondent "Philaletes" in our next.

Dr. Yates's Appeal.—This gentleman having placed himself in a most nauseous predicament with reference to some late proceedings at the Aldersgate-street Dispensary, now finds his situation "too hot to hold," and has inserted a reclamatory "peccavi" in the

newspapers, begging the profession to take him back again; but he has gone too far, and must console himself with the delightful knowledge, that no one can touch pitch and not be defiled. The only reasonable excuse we can make for him is that he is young and as yet inexperienced.

New Work on Geology.—A celebrated professor will shortly publish an Anatomico-Geological Description of an Oyster-bed found in the stomach of the late Mr. Dando.

Female Education.—Let them rise early and retire early to rest, and trust that their beauty will not need to be coined into artificial smiles, in order to ensure a welcome, whatever room they enter. Let them ride, walk, run, dance in the open air. Encourage the many and innocent diversions in which the young delight; let them, under proper guidance, explore every hill and valley; let them plant and cultivate the garden, and make hay when the summer sun shines, and surmount all dread of a shower of rain, or the boisterous wind; and, above all, let them take *no medicine*, except when the doctor orders it.—*For. Quart. Rev.*

Intestinal Rail Road.—A contemporary, anxious to amuse his readers, inserted a case of chorea a few weeks since, in which the patient is stated, somewhat ironically, to have taken some few hundred pounds weight of carbonate of iron. The author's object in writing the paper was, we understand, to show the practicability of laying down a rail-road between the stomach and the rectum, with a view to establish a quicker communication between these important parts, thereby upsetting all Dr. O'Beirne's "Views" and his "Defecation" to boot.

Dr. Stratten and Herr Hahnemann.—We have received a very angry and vituperative letter from the former of these gentlemen, and by the twenty hundred millionth part of every drop of Irish blood that is in us, both he and Hahnemann shall be immortalised, *secundum artem*, in our next Sanctum.

Perpetual Motion.—A correspondent, whose signature is "Chrchichrononhotonthologos," writes in great glee to assure us, that, after much labour and study, he has succeeded in discovering a plan of perpetual motion, this is it, to put a man into a tub of hot rappee snuff, and let him sneeze away till he sneezes his life out. We doubt much whether our correspondent performed the latter part of this experiment.

Effects of Electricity.—If the diaphragm be made part of a circuit of a charge equal to two feet surface, the lungs make a violent effort, followed by a loud shout, but if the charge be small it never fails to produce a violent fit of laughter; the comic effects of electricity are quite irresistible.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

VOL. IV.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LVIII., DELIVERED FEB. 25, 1833.

GENTLEMEN,—I was mentioning on Friday evening, that aneurisms of the abdominal aorta do not generally produce so much injury and disturbance of the viscera which they compress, as thoracic aneurisms do of the viscera in the thorax; a fact which is explained partly by the circumstance, that the parietes of the abdomen are more yielding than those of the chest, and partly by the consideration, that the abdominal viscera will bear a good deal of pressure, without any serious inconvenience, which is far from being the case with the organs situated in the thorax. However, do not imagine that aneurisms of the abdominal aorta are not sometimes attended with symptoms of great severity, for the tumour may interfere with the descent of the diaphragm; it may so injure the spine as to cause paralysis of the lower extremities, (though the latter is a very rare case, an instance of which, however, is recorded in one of the volumes of the *Lancet*;) there may also be acute pain, caused by the pressure of the tumour on the hypogastric plexus of nerves; and there may be various ailments, very similar to those of a lumbar abscess, a circumstance which sometimes renders it difficult to make out the nature of the case until the tumour presents itself externally. Sometimes the pressure of an aneurism of the abdominal aorta will produce a change in the shape of certain organs within the abdomen; thus, the liver may be altered in its shape, and also the kidneys, a fact which is illustrated by one of the preparations before us. Here you see two large sacs, one on each side of the lumbar vertebrae, which have produced extensive ravages in the bones of the spine, and yet

have left the inter-vertebral substance tolerably perfect; these tumours, you see, have pressed on the kidneys so as to alter their shape. The preparation is curious on another account, which is, that the disease was not suspected until a short time before death, when symptoms of internal hæmorrhage suddenly came on, from the bursting of one of the tumours into the peritoneal cavity. A short time afterwards, a swelling appeared in the front of the abdomen, in consequence of some of the blood having passed to the external side of the peritoneum, between it and the muscles of the abdomen. In the pelvis the bladder had also been compressed by the descent of the mass of coagulated blood contained in the peritoneum. Here is an aneurism of that part of the aorta which is situated between the crura of the diaphragm; two portions of the swelling extending into the chest, and another downwards below the diaphragm. The aneurism ultimately burst in the chest. One circumstance respecting aneurisms of the aorta, deserving of your attention, is, that they sometimes implicate its principal branches; thus, there is a preparation on the table, showing an obliteration of the mesenteric and renal arteries, in consequence of disease of the aorta; and you will find in the museum one specimen, which ought to have been brought into the theatre this evening, exhibiting an obliteration of both mesenteric arteries, so that the supply of blood to the intestinal canal must have been chiefly through the hæmorrhoidal artery. This is all that I have to say of aneurisms, until we come to the operations.

Gentlemen, continuing the subject of *diseases of blood-vessels*, I next arrive at those of *veins*. The difference in texture between veins and arteries, and the more moderate impetus of the blood in the former than in the latter, would lead us to expect a considerable difference in the diseases of the two systems; and this you will find to be the case. In the first place, the veins are not liable to any disease which strictly deserves the name of aneurism, that is, to a tumour filled with blood, arising from a wound in, or a disease of, the coats of the vessel, and increasing

VOL. IV.

Y

from the impetus of the blood circulating within the vein itself. You have, indeed, a disease called *venous aneurism*; but this is produced by the impetus of arterial blood transmitted into the vein, in consequence of an accidental communication having been established between such vessel and a neighbouring artery. This is not, however, a disease strictly meriting the name of aneurism, which is preceded by disease of the coats of the artery, or by a wound of them, and is kept up by the impetus of the blood, which naturally circulates in the vessel itself. The arteries, as we have seen, are very subject to calcareous depositions between their internal and middle coats, especially in elderly persons; but this form of disease is uncommon in the veins, nor can this peculiarity be always explained by the differences of texture between the two classes of vessels, for the pulmonary artery is very much like the aorta in structure, and the right cavities of the heart bear a considerable resemblance to those of the left; yet the right cavities of the heart and the pulmonary artery are rarely affected with calcareous deposition, while the left cavities of the heart and the aorta are frequently the situations of them. I do not mean to say that the veins are completely exempt from calcareous deposition; and here is a preparation, demonstrating a portion of the femoral vein, with a considerable deposit of calcareous matter upon it, and the surrounding cellular substance condensed and thickened; but cases of this kind are rare, and I believe this is the only example of such disease in the museum.

The veins are more frequently blocked up by coagulable lymph and coagulated blood than the arteries; and here you see a preparation, in which the left iliac vein is completely blocked up with lymph. An impervious state of the veins from this cause is a frequent occurrence. There is a preparation on the table, in which the left subclavian vein is blocked up in the same way.

Pus is also more frequently found in the veins than in the arteries; this is a circumstance deserving your notice, and is explained by Andral in the following manner:—pus, he conceives, may get into the veins in two ways; in the first place, he thinks that it may be conveyed into them from other parts, in which it has been originally formed; and in the second, that it may sometimes be formed in the vessels themselves. On the other hand, he believes that pus can only get into the arteries in one way, namely, by being formed within them. If this theory be true, it gives some explanation of the fact; but Professor Andral might also have taken into consideration another truth, which is, that the veins are more prone to inflammation than the arteries; this is a circumstance, which of itself would go a great way in accounting for the greater frequency of purulent collections within the venous, than the arterial system.

While wounds in arteries give rise to such hæmorrhage, as is often dangerous and even fatal, the bleeding from veins is in general easily controlled. We purposely open considerable veins for the relief of diseases, and find no difficulty in stopping the flow of blood from them, in fact, the bleeding stops directly the fillet is removed, so as to allow the blood to pursue its usual course towards the heart. But even when more trouble is encountered, the bleeding is much more controllable than arterial hæmorrhage, or rather, it does not require the same means to stop it; hæmorrhage from any vein, which admits of being compressed, may be stopped with facility and certainty by this proceeding, but it is not so with hæmorrhage from a considerable artery. Indeed, I should say, that whenever the bleeding from a large vein is troublesome, pressure is the right mode of stopping it; it is preferable to a ligature; for you will find, in the course of my observations on the diseases of this system of blood-vessels, that ligatures cannot be applied to veins without a disagreeable risk of inflammation of their texture, which spreads with rapidity, and is often attended with dangerous consequences. All good practical surgeons, therefore, now avoid tying veins, unless their bleeding cannot be stopped by other means.

I have already told you, that veins are very prone to inflammation, and that it spreads with considerable rapidity, from the point at which it commences, often following the course of the circulation within the vessel, as far as the vena cava, and sometimes even to the right auricle of the heart itself. This kind of disease, termed *phlebitis*, has attracted more attention in modern times, than it did some years ago; it is found that many persons die of it, and that it has a share in various diseases of a serious and fatal character. I must give you one caution, however, which I gave you with respect to the arteries, namely, not to consider every redness of a vein a proof that there has been inflammation of the vessel; for, on examining veins a few days after death, you will frequently find a red tinge on their internal lining, which is not to be confounded with the effects of phlebitis. It is known, that this red tinge is even more quickly produced in the veins than the arteries. Inflammation of veins is always disposed to spread in the course of the circulation; but it may also extend itself in the opposite direction. Phlebitis sometimes produces an effusion of lymph in the cavity of the vein, so as to cause an obliteration of it, and the vessel is then converted into a solid cord. Here is a preparation of the vena saphena major, which has been thickened by inflammation and partly rendered impervious. Sometimes one consequence of phlebitis is the formation of pus in the vessel; the matter is then either mixed with the blood, or is bounded and circumscribed in distinct cells, in consequence of adhesive inflammation between the different

collections, so that there is a chain of abscesses in the track of the vein.

When phlebitis is of trivial extent, the symptoms are not very different from those which attend a limited degree of local inflammation of a common kind. But, when the inflammation extends far, the constitutional symptoms assume a dangerous character; the pulse becomes rapid, irregular, and feeble; the respiration hurried; the tongue at first dry, and afterwards brown; and the patient is afflicted with great thirst and nausea, and, in many instances with a copious vomiting of bilious matter; he also complains of a considerable oppression at the heart, or about the præcordia, as the phrase is; the countenance is expressive of considerable suffering and anxiety; the strength is reduced to the lowest degree, and throughout the whole course of the disease, the spirits droop in an unusual manner. This disease frequently advances in a short time to a fatal termination; the patient sometimes maintaining the struggle for four or five days, but sometimes not longer than two or three; and I may say, that he does not often survive a week, if the disease take an unfavourable course, which I am sorry to remark is too often the case.

When you examine a limb, in which phlebitis exists, you will find the veins have a hard feel, and are exceedingly painful on pressure; and the skin over them is of a dark red colour, owing to the extension of the inflammation to the surrounding cellular membrane. Sometimes the whole limb is cedematous, and enormously enlarged, and frequently matter is found collected in cavities about the veins chiefly affected, and when this happens there is generally more or less sloughing of the cellular membrane. When the inflammation stops in the cavity of the vein, one circumstance having an influence in forming a boundary to the inflammation, seems to be the junction of another venous branch with the inflamed vein; at all events, when the inflammation stops, it is generally at such a point.

In phlebitis, nothing is more common than for pus to form in parts remote from the original inflammation; thus when there is phlebitis in one arm, nothing is more common than the formation of an abscess in the opposite axilla. In some instances, there are depositions of pus in the internal viscera; and you will often find abscesses in the liver, the lungs, the synovial membranes of joints, within the pericardium, or within the cavity of the pleura. Now the explanation of the cause of these distant or secondary abscesses is rather difficult; it is a subject that has never yet been satisfactorily made out; but the fact that they do take place is well deserving of attention, because it is principally when these depositions take place, that the disease takes a fatal course. Various attempts have been made to explain the origin of these secondary formations of matter, but a considerable degree of obscurity

yet prevails. Some pathologists consider that they are absorbed or translated from the original seat of the inflammation to the places of the secondary abscesses; some refer them to the operation of a deleterious principle in a wound; and others consider them to depend on the various sympathies, which exist between the different parts of the body; but I may say, that hitherto no satisfactory account has been given of the causes of these distant collections of matter.

Phlebitis mostly occurs from an accidental wound or from a surgical operation, such as amputation, venesection, &c. A prick of the femoral vein in the operation for popliteal aneurism has been known to cause a fatal attack of phlebitis, the inflammation extending up the external iliac, the common iliac, and the vena cava, in which a diffused species of inflammation was observable as high as the heart. On this account, the application of a ligature to the femoral vein after amputation is objectionable, such an irritation of the vein having sometimes excited a fatal attack of phlebitis. It is true, the same consequences sometimes result from the simple wound of the vein in amputation; but they are much more likely to occur, when the irritation of the wound and that of the ligature are combined. Few surgeons of eminence and judgment approve of tying the femoral vein. How many instances of fatal phlebitis have arisen from the operation, formerly so common, of tying the vena saphena major in cases of varicose veins of the leg; indeed the knowledge of these fatal cases has now led to the rejection of the practice, and we scarcely ever hear at the present day of such operation being performed, though twenty years ago, it was done almost every week in every hospital in London.

Numerous observations prove, that the painful enlargement of the lower extremities, termed *phlegmasia dolens*, which comes on two or three weeks after parturition, depends upon inflammation of the iliac and uterine veins. This is well proved in an ingenious paper by Professor Davis, published in the *Medico-Chirurgical Transactions of London*. This is a preparation, I think, put up by Professor Davis, showing the changes which have taken place in the large veins in such a case. Velpeau also found the iliac and femoral veins full of pus in *phlegmasia dolens*; and many instances in which women perish in child-birth are found to depend on inflammation of the veins of the uterus and ovaries, and of the iliac veins, all being either obstructed by lymph, or full of matter; in fact, they are cases of phlebitis, and we must therefore refer the death of the patients in such examples to that cause. Many cases, going under the name of phlegmonous erysipelas, and diffuse inflammation of the cellular membrane, seem to be attended with a very strongly marked degree of phlebitis. If I had had Cruveilhier's plates here, I might have pointed out to you several remarkable effects of phlebitis; but as, by some

omission, they are not on the table, I will show you them at the next lecture.

I am sorry to say, gentlemen, that the treatment of phlebitis, is not well understood; at least, the methods of treatment, hitherto in use, have not had much success. In the beginning, when the disease is in one of the limbs, it is mostly judged advisable to apply a good number of leeches to the part. As for venesection, it is not universally adopted, and many practitioners are timid about it, in consequence of phlebitis being soon combined with the greatest prostration of strength; the symptoms indeed becoming very similar to those of some stages of typhoid fevers. An apprehension has consequently prevailed, that venesection might reduce the system too rapidly. However the best surgeons all concur in recommending the free use of leeches in the early stages, and also the administration of purgatives and antimonials. Yet, I ought to explain, that there are some very good surgeons, who instead of adopting the above practice in every particular, place their whole reliance on local bleeding in the commencement, and then in the free exhibition of calomel and opium, employing fomentations as a local application; this practice is sometimes preferred to the administration of common purgatives and antimonials. Cold applications in the beginning of phlebitis seem to be indicated, and it is a question, whether they are not superior to the fomentations and warm applications, which are more commonly employed; I believe them to be deserving of fairer trials than they have generally had in cases of phlebitis. You will find, however, that fomentations often afford considerable relief, and certainly they are more fashionable than cold applications. When you have reason to believe that there is matter in the cavity of the veins, and that the collections are bounded in the manner I have explained by the adhesive inflammation, then the indication is to discharge them, by making a proper opening. I ought to mention, that John Hunter thought, that inflammation of the lining of the veins might be prevented from extending upwards, by employing pressure above the wound in the vessel, so as to excite the adhesive inflammation in that situation. This seems rational; but generally, the inflammation has extended too far when such a plan is thought of, and we do not hear of its being put in practice. I may say, that, on the whole, the treatment of phlebitis is very unsuccessful, and that there is great room for the further investigation of the subject.

The veins are liable, as I have observed, to *varicose aneurism*, *venous aneurism*, or *aneurismal varix*, as it is called. This is a swelling of the vein, arising from the passage of the blood into it from a neighbouring large artery,—generally from the blood of the brachial artery passing into the median basilic vein, in consequence of a communication being formed between those vessels in the unskilful performance of phlebotomy. The blood then

gushes from the artery into the vein, and produces, as you may observe in this cast, a bluish tumour, which you find will pulsate, or vibrate, under your finger. On applying the ear, you may also perceive a hissing sound, which is produced by the passage of the blood into the vein. The vein soon enlarges to the size you observe in this model, namely, about the size of a pigeon's egg; and it rarely becomes larger, for, after it has attained this size, it usually becomes stationary. It produces, also, enlargement of the adjoining veins. You observe, here, that the swelling extends up the basilic vein, which, having to return more blood to the heart than natural, obeys that law of nature which prescribes, that when a blood-vessel has to carry a greater quantity of blood than common, it shall enlarge in proportion. In cases of varicose aneurism, the veins, as is well exemplified in the cast, acquire a tortuous appearance. This drawing shows the thing still better. The pulse at the wrist is always feebler than in the natural state of the limb, because some of the blood which should go to the radial artery is conveyed into the vein at the bend of the arm. Another consequence of this circumstance is an emaciation of the lower part of the arm, which is also readily affected by exposure to cold; and its temperature is lower than natural. In addition to these particulars, gentlemen, I may inform you, that the brachial artery itself becomes enlarged. In this instance (*showing a plate representing the dissection of a case*) the brachial artery bifurcated high up the arm—it is therefore double—which explains why it is not so much enlarged as it is under other circumstances.

But the disease is not always so simple as I have described it; there is not always a simple tumour of the vein; but, in many instances, there is formed between the vein and the artery a sac, which is in reality a false aneurism of the artery; and then the blood passes first into the sac, and thence into the vein. Here is a drawing of such a case, taken from one, which was under the care of Sir C. Bell. The brachial artery bifurcates high up; and you see there are two aneurisms, one a venous, and the other a false, aneurism, in the cellular substance under the fascia. In these cases, the lancet transfixes the vein and fascia completely, so that there are two openings in the vein, and one in the artery: the outermost opening in the vein heals, and the other is kept open by the continual passage of blood through it from the artery.

Gentlemen, experience proves, that other large veins besides those at the bend of the arm may become affected with this disease; there are instances of its having occurred in the arm towards the axilla, in consequence of a gun-shot wound; for, when a musket-ball passes between the axillary artery and the vein, it may produce a communication between them; and the same thing may take place in the thigh, from the passage of a ball between

the femoral artery and vein, examples of which are on record. There is only one instance related of an aneurismal varix having been produced between the aorta and the vena cava, and that is described by Mr. Syme, in the 36th vol. of the *Edinburgh Medical and Surgical Journal*. The case was produced spontaneously, or rather from disease, and the communication between the artery and vein took place just above their bifurcation into the iliacs.

Now, gentlemen, with respect to the treatment of aneurismal varix, I have explained to you, that the disease becomes stationary when the tumour has reached a certain size, and that, when the vein alone is concerned, that is, when the swelling is produced by the mere dilatation of the vein, without any aneurism underneath it, there is merely a weakness of the limb, some loss of its power, a degree of emaciation of the hand and fore-arm, and an inability to maintain its temperature as well as usual. Now, as these are the worst inconveniences which the individual suffers, it is hardly judged advisable, in common instances, to recommend an operation. If you were called in to a case in its early stage, you might try the effect of pressure; for if you could succeed in obliterating the communication between the artery and vein, you would effect a cure. Sir Astley Cooper mentions, in his lectures, the case of a young lady, whom he cured by compression; and I will show you a preparation at the next lecture, taken from a case, in which a cure was accomplished by the same means. In the example from which this drawing and its corresponding preparation were taken, and which was under the care of Sir Charles Bell, he judged it necessary to perform the operation; and, on account of the high bifurcation of the brachial artery, he was obliged to tie both branches of it; mortification followed, however, and the man died. Another instance was communicated to me by Mr. Atkinson, of York, in which he tied the artery; the result here, also, was mortification. These disasters should teach you that the operation ought not to be performed on light grounds. If the tumour should increase in size in a great degree, and produce much inconvenience, then you might operate; and if there were an aneurism between the artery and vein, the operation might be called for, in the same manner as for a common aneurism of the brachial artery.

INTRODUCTORY LECTURE

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S., &c.

At the Medical School, Little Windmill St.

Wednesday, October 2.

This is, I believe, gentlemen, the seventeenth time, I have had the pleasure of addressing you as your teacher of surgery, and as the

span of human life is but small, it is possible it may be the last. I shall, therefore, avail myself of the privilege allowed in such a lecture, and endeavour to make you acquainted with my views and opinions on several subjects which have not hitherto been included in it. I trust it is the last time I shall have occasion to address you in such a manner, that I shall not have cause to do it, for the charge of ingratitude is of so serious a nature, that few can be found who will acknowledge themselves to be guilty of it. It is always painful to me to speak of myself, it is particularly so at the present moment, but I am forced to do it in consequence of statements which have been made, not only from the medical press but in a weekly newspaper, and if I were not to point out their inaccuracy, it is possible that gentlemen, from frequently writing these things, might not only succeed in persuading themselves they were true, but possibly induce other persons to believe them. Some of the points I shall allude to do not concern you, but as others do I shall make one affair of it, and take care that it finds its way to the public through the medium of the medical press, that my professional brethren in the country may know me as I am, and not as I am represented to be. In the newspaper I am said to be a person endowed with the greatest vanity, and with a degree of self admiration that is not to be exceeded. It may be so, gentlemen, for we are none of us conscious of our own faults; I only acknowledge that I am vain upon two points. 1st. That I have never written an anonymous letter or paper reflecting on the character of any one. 2nd. That I have never said one word behind any man's back that I have not said before his face. When I was in Spain, confidential reports were called for by the head of the department from all the inspectorial officers. I believe the practice prevails throughout the army at the present time, or did so until lately, if it does not do so now, and a man's hopes and expectations may be injured, if not blighted, by a little private malice or negligence. I never would write a confidential report, and when asked why, I always replied, you get letters enough I am sure from me in favour of those who deserve them; when there is nothing to be said for a man, I take no notice of him, and when he deserves punishment or animadversion, I always convey it in a public letter which every man can see, the individual thus knows all the charge against him, and can take such steps as he pleases to meet them. That I am vain upon these points, I acknowledge. I submit very willingly to its being said so, and only wish others would have the same vanity, the same admiration of themselves. There would have been a great deal more happiness and good will in the profession than there is at present. In regard to the observations which have been made on the length of my head or the width of my tail, my beauty or my ugliness, my voice or my manner, they are all at the ser-

vice of any one who chooses to remark upon them. I can laugh at a shaft of satire, although it be directed against myself; it may be even keen, provided it is only playful. There was only one point in the newspaper at which I felt hurt. The compliments far outweighed the little follies attributed to me; they were much more than I deserved, than I believe I merited, and, with the one exception, I laughed at the whole as much as any one else could do. The exception was, the statement which referred to the late Mr. Brookes. It is said, that I, as President, was authorised by the College to treat with Mr. Brookes for the purchase of his Museum. He asked 10,000*l.*, and I, in my great meanness, would only give him 7000*l.* Let me state the facts, they may as well be known. Mr. Brookes never made a public offer to the College of his Museum at any price; it therefore never became a subject for consideration by the Council. He offered it privately to one of the curators of the Museum for 10,000*l.*, and these gentlemen having considered the matter as privately, replied that it was not worth that sum. I do not believe they wished to have it at any price; they had no place to put it in, no person to take charge of it; and they must have sold two-thirds of it, had they purchased it. They offered, however, to purchase, at a valuation, such part of it as would be a useful addition to the Hunterian collection. Mr. Brookes would not hear of such a proposal, and this private negotiation dropped. I was then only a junior member of the Council, filling no other office, and in rather bad odour with those elderly gentlemen, most of whom are now no more, but who then governed the College in a manner which cannot occur again. With Mr. Brookes I had little in common; I had not been his pupil; I was not a friend but only an acquaintance, who had a great respect for his long and unwearied labours in cultivating and teaching anatomy. I saw that his health was breaking, that he was far advanced in life, and unable to continue his lectures, and I understood that he was so poor as to render the sale of his Museum a matter of necessity. Meeting him accidentally, I spoke to him on the subject, and suggested that he should make the offer of his Museum a public one, by addressing his letter to the President and Council, and that he should ask the exact sum he meant to take and no more. He said his pride in his Museum would not let him ask less than 10,000*l.*, and that had been refused. I laughed at the pride of the business, and pressed him to say what sum he would take. He said at last, if the College would offer him 7000*l.* he might perhaps be induced to take it, but I could not persuade him to make the offer. I told him I thought the Council might decide in his favour, even if the Board of Curators did not recommend the purchase. I promised him my best assistance both publicly and privately, but nothing could induce him to make the offer, and this, my private negotiation,

failed also. You know the result; the Museum was sold by auction, and the College was one of the best purchasers: but the sale put into his pocket scarcely one-third of 7000*l.*, and he died so poor as not to leave enough to pay his funeral expenses. A relation of his called on me a short time back, as the president, to propose a subscription for a print or bust, by which means the money might be raised. He wished to have it headed by a subscription from the College; but, as the Council have it not in their power to give money for any such purpose, I advised him to send two copies of the portrait as a present for the Library. They were accepted, but ordered, under the particular circumstances of the case, to be paid for. My own mite was given without taking a proof, with the hope that the demand from Mr. Brookes' friends and pupils would be so great, as soon as the nature and object of the subscription were known, that there would not be sufficient copies to answer it. These, gentlemen, are the only meannesses I have been guilty of towards Mr. Brookes.

There is another point on which I shall take this opportunity of righting myself. I am called a high tory and conservative both in public and in medical politics. With the former I do not interfere, and in both I have no objection to be called a tory and a conservative; they are, in general, very respectable persons; but if it is meant as it really is intended, to hold me up to the profession as a person who has supported all abuses, and has endeavoured to maintain the existence of those proceedings which have been obnoxious to it, I must say that I am neither a tory nor a conservative, but, I fear, a regular radical. We will take two examples from numerous others. A few years ago no man could teach anatomy or surgery in London unless he was surgeon to an hospital, or was patronised by the medical officers of an hospital as a teacher selected by them. This was a hardship; labour, talent, ability, learning—all were in vain; nothing would do but patronage. Many men protested against it, but the authorities would not yield for a long time; at last, however, they did. Who fought this battle? A person who was content to assist in removing the evil without taking unto himself any peculiar merit for doing so; whose private interest, perhaps, would have been served by announcing himself as a champion of the profession on this point, but who preferred being quiet and unostentatious, if he could be permitted to be so. Do you believe this concession was made without a contest; that the old gentlemen, now nearly all no more, who thought the regulation a good one and for the advantage of the public, yielded without a struggle? They did not; they made a very tough fight of it, and yielded, but not without designating the person who moved the consideration of the matter, a radical of the first water, a man who had not the slightest veneration for any ancient institutions—their Joseph Hume.

Some of the surgeons in the country thought they could teach anatomy and surgery almost as well as their more fortunate brethren in London; they had done so for years, and wished their courses of lectures should be recognised by the College. This was not done until after many contests, not until after the table of the House of Commons was loaded with petitions on the subject. At last the College altered its regulations. The courses of surgery were first allowed, the year, after those on anatomy, &c. &c. Who principally fought this battle, who first moved that the concession should be granted; why your humble servant, the great tory, the staunch supporter of all abuses. I believe as great a change was effected in medical politics by the alteration of these two regulations, as in general politics by the Reform Bill. Yet my vanity never induced me until now to tell you, or the profession, of the share I had in effecting it. It would have been profitable to me to have done so, but I was content to do that which I thought my duty without blazoning it to the world at large. You would not have heard of it now, if it had not been for the obstinate perseverance exhibited by some persons, who have the ear of the medical press, and it appears now of part of the public press, in exhibiting me in colours to which I lay no claim. I have no desire to be called either a medical or a political reformer, but I wish to be spoken of, if I must be spoken of at all, as one who is foremost in endeavouring to correct any and every abuse wherever it may be found, that comes within his province. It is not consistent with the profession of a medical man to interfere with politics. I never do. And the government will do well in taking care not to make the doctors a political body, they will repent it but once if they do.

I have made it a rule through life neither to accept nor to hold an office if I did not find it convenient to do the duties of it, as they ought to be done, at least to the best of my ability; and it has not been without great regret that I have seen it stated, that I have, by absenting myself from the Westminster Hospital, neglected the poor committed to my care. I shall clear up this point. Some charges of want of attention were made a few months ago against some of the medical officers of the Hospital, with probably as much truth as those which have been repeated against me. The Weekly Board of Management thought it right to order, that the physicians and surgeons should write their names in a book every day they came, with the hours of their attendance, &c. All obeyed except me. I positively refused to do any such thing. Mr. Wood, one of the committee, came to me and said, that the committee regretted to find I was obstinate on this point, and particularly so as nothing was intended towards me; that they knew and duly appreciated my attention to the poor; they knew I often came three or four times a day when I thought it necessary

to do so; and that it was the more painful to them to think that it was with me they must dispute the matter. My reply was, that I had no personal objection to write my name in the book, but that it was derogatory to the profession I followed, and the place I held in it; it was usual for the lower clerks in a public office to do so, or in a merchant's house, but the confidential persons were always excepted from this regulation. The physicians and surgeons of an hospital were confidential persons, and ought to be treated as such; if they failed, reprimand or dismiss them, but do nothing derogatory to the character of their profession. A doctor should at least be a gentleman in principle and in manner. The affair ended by my desiring the house surgeon to report weekly the number of my visits. The committee saved their dignity, and have wisely and very honourably to themselves refrained from asking for either book or report, satisfied that if any neglect had occurred it would not be repeated. It should be known that they only require two visits a week from each medical officer. I hope my professional brethren in the country will believe hereafter that I neither neglect the honour and character of the profession, nor my duty to the poor. As to what a doctor may do on these points the public in London care nothing, and I do not give myself the least trouble about their opinion. All they want is to be cured when they are ill, and they care little by whom or by what means, or by what kind of men, so that it is done.

When I commenced the lectures last year I addressed you in the following words. I shall lecture on Mondays and Wednesdays in each week, from the 1st of October to the last day of April, and on Fridays when there is not a Court of Examiners. You are entitled to sixty lectures and no more, they will be on what subject I please and as I please, and I will not lecture in May, even if the course be only half completed. If you do not like this, gentlemen, do not come to me. I do not wish you to do so unless you are satisfied it will be for your advantage; and clearly understand, that you are entitled only to what I please to give you. Now, then, what did I do from Christmas to May? I lectured three, four, and five times a-week, giving more than eighty lectures instead of the promised sixty; and, in the month of April, to my own very great inconvenience. When the last day came, I said, "We have been obliged to hurry over the last two or three subjects, and the diseases of the eye have not been noticed. Come to the Ophthalmic Hospital every Friday, see all that is to be seen; I will make some clinical remarks to you afterwards, whenever I have time, and you will, I hope, reap a greater advantage than you could do from the delivery of a few dry lectures here without the opportunity of seeing the diseases themselves." For all this trouble and kindness one of you has thought proper to write a letter abusing me in

the *Lancet*, and to do it at the commencement of this session, warning students not to come to my lectures; I am afraid he must be one of the gentlemen who have some crosses against their names in my list for absence when it was called over, but whether it be so or not let us understand each other. If any one believes I lecture here for gain in money it is a mistake. The class last year consisted of one hundred persons, sixty paid, the remainder belonging to the army, navy, old pupils, &c. did not. Of the sum received about 120 pounds came to me, after paying all expenses. When solicited to lecture at other places, where I might perhaps have got three times as much, I have always refused. I would not go one mile further from home for the money, I would not expose my servants and horses to the cold for it, it is no object to me. The favour of the public, much I am willing to acknowledge above my desert, which has given me a large and annually increasing income, has rendered it unnecessary. I lecture, then, gentlemen, upon principle. I owe to the medical department of the army a great debt of obligation. It is to them I am indebted for the situation I hold in this metropolis; to those who served with me and who supported me afterwards. It is little I can do for them, but I can assist their successors; when they want information I can obtain it for them; when they wish to renew any part of their knowledge I can assist them, and instead of being sneered at, as they often were, some 20 or 30 years ago, for some trifling defect, by men who did not know them, they, and all other officers in the public service, find in me a friend, I wish I could say as capable as he is willing to befriend them. As Surgeon to the Westminster and the Royal Westminster Ophthalmic Hospitals I think it right, whilst I have health and strength, to give some public instruction, until younger men shall arise in each capable of taking my place, when it will be most readily resigned. So far from money being my object, you all know that the door of my lecture room is never closed. That no one is ever asked for his ticket or his name. You know that some gentlemen have regularly attended for a whole season without one single word being said to them, and some have even tried my good nature so far as to ask me for a certificate at the end of it, even without paying the fee. I have never refused it after being satisfied, on inquiry, that they had duly attended. I only said to them you have done wrong, you have hurt your own feelings unnecessarily, and have acted unkindly towards me. I have always said, at the conclusion of my introductory lecture, that if there were any one who wished to attend, but who had not the means, to come to me and say so, the application should never fail. It is the misfortune of a gentleman to be poor but not a fault. Why did you not avail yourself of it? When you have wished to attend the practice of the hospital, without having the fee ready, have you ever been

refused? When your year has expired, have the surgeons ever refused you the certificate of attendance, without receiving the money, if they knew you had it not to give? Some of you, who have attended during the last ten years, can best answer the question. I can only say, that there are some few in the profession, men whom I value as friends, whom I respect and esteem, who were under these circumstances. I am aware that in every flock there may be a black sheep, I regret there has been one among you, I regret more that the press will allow such charges to be made without knowing and without giving up the name of the author. It obliges me thus most painfully to speak of myself. It is for the last time I shall never again notice for attacks of the kind, satisfied that those of my professional brethren in the country, who do not know me, will not believe them if they should be written.

In taking leave of you this evening, I again beg to repeat that I do not seek you, but that you seek me; I have issued no advertisements, either in the newspapers or the medical journals; I have not even a prospectus printed. I have not taken the least trouble to induce a single individual to attend; and, I hope, we now fully understand each other. I have only to add, that I am punctual, and have a great objection to the door being opened after I have begun the lecture, and it is but due to you to say, that I am perfectly satisfied with, and highly sensible of, the constant marks of respect and attention I have invariably received from you in this room, and on all public occasions.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XIV.

Peritonitis from Perforation of the Stomach and Intestinal Tube—Pleuritis from Fracture of the Rib.—Pericarditis combined with Hepatic Disease.

GENTLEMEN,—We left off at our last lecture in considering the history and pathology of that form of peritonitis which results from a perforation of some portion of the intestines; and the escape of its contents into the cavity of the peritoneum. You remember the circumstances of a remarkable case of this form of the disease which was some time ago in the hospital. The patient had been labouring for a considerable time under symptoms of a decided stomach affection; in other words, he had severe pain, pyrosis, and loss of appetite. On a sudden he experienced a violent attack of pain in the belly, and remained in this state for twelve hours, when he was admitted into the hospital, presenting all the symptoms of the last stage of peritonitis. From a careful

review of the circumstances of the case, we made the diagnosis of perforation of the stomach. The reason why we came to this conclusion (which was afterwards verified by dissection) was, that the man had been subject for a long time to an affection of that part of the tube. You may also recollect another very curious circumstance connected with this case, which I have not noticed in my last lecture. The pulse was completely absent in the radial, and could scarcely be felt in the carotid arteries, while, at the same time, it continued plain and even full in the femoral, a circumstance which, along with others, strongly confirmed our suspicions of severe abdominal inflammation. I wish to call your attention to this fact, as I believe the phenomena of the large vessels of the abdomen, in cases of visceral inflammation, have not been sufficiently attended to; and that this source of diagnosis has been neglected. You can easily conceive the reason of the increased action of the abdominal vessels, when you recollect how remarkable the pulsation of the digital arteries are in whitlow, and of the carotids in disease of the brain. We are, therefore, in the habit of looking on an increased throbbing of the abdominal aorta as one of the signs of disease of the abdominal viscera. I do not say, that your diagnosis should depend exclusively on this point, for we often find this pulsation where no visceral inflammation exists; but, when along with fever and other signs of disease of the intestines, we find a want of proportion between the action of the abdominal vessels, and those of other parts of the system, I think we are authorised to consider this throbbing as one of the symptoms of intestinal disease. In the case I have just mentioned we could not easily feel the abdominal aorta, but we could feel the femoral vessels pulsating with great violence, from which we could judge that the abdominal aorta was in a state of excitement, and this strengthened in a remarkable manner our notions of the existing disease. You remember this was verified by dissection; we found universal peritonitis and a large quantity of yellow fluid in the peritoneum. We examined the whole of the intestinal tube without discovering any perforation, but at the lesser curvature of the stomach, near the pylorus, we found a hole about the size of a kidney bean, through which a portion of the contents of the stomach had escaped into the peritoneal sac. You perceive, then, that our diagnosis was correct; here is the preparation, which I have shown you on a former occasion. You will remember, that, at the time of this occurrence, I drew your attention to the principles on which our diagnosis was founded; they were precisely the same as those by which we judge of the sudden solution of continuity in other parts from the occurrence of a new train of symptoms rapidly supervening on the original mischief.

I said that perforation of any part of the intestinal tube might arise from acute or chronic disease, but that, in the majority of instances,

it is produced by circumscribed ulceration, the result of acute disease. I also mentioned that, for the most part, intestinal perforation, when caused by chronic disease, was seated in the stomach, and when brought on by acute disease, in the small intestines. I endeavoured to explain to you why perforation, from acute disease, should be more frequent in the latter situation than that which is produced by a chronic affection of the intestinal tube. Chronic affections of the stomach are much more common than those of the intestines, and when a chronic disease has been going on for a considerable time, the parts adjacent become thickened and adherent, the ulcerative process is lessened, and before the serous coat is perforated there is time for adhesion between it and the opposite peritoneal surface, and thus its contents are prevented from being effused into the cavity of the peritoneum. Under such circumstances, also, it sometimes happens that false passages are formed between two distinct portions of the intestinal tube, as between the stomach and colon, without any escape of matter into the peritoneum. But when the contents of any portion of the intestinal canal get into the peritoneal sac, what have we to do? I believe very little. When such an occurrence takes place, you may, generally speaking, expect an universal, sudden, and fatal peritonitis. There is a quantity of extraneous matter poured into the peritoneum, and as long as the fistula remains open, and the action of the intestines continues, there will be a constant effusion of their contents. You can, therefore, easily understand the termination of such a case. One of the best authors, who has drawn the attention of the medical profession to this point, is Louis, and as his remarks are very valuable, I shall read his diagnosis. After giving a description of the disease, he says:—

“At a certain period of the disease for which the patients entered the hospital, they were suddenly attacked with both an acute and tearing pain in the belly, soon followed by alteration of the features, nausea, and vomiting. These symptoms lasted, with various degrees of violence, from twenty to fifty-four hours, presenting remission more or less considerable, and pointed out an intense peritonitis, suddenly produced.”

From these circumstances he has drawn the following rule, which is, generally speaking, a good one. “If,” says he, “we have a case of acute abdominal disease, in the progress of which some unusual symptoms appear, if there occur, all of a sudden, violent pain which continues to increase in intensity, and this be followed by a rapid alteration of the countenance, with nausea and vomiting, we may believe and announce that perforation of the intestines has taken place. Also, if a patient, who has been lying in bed under some abdominal affection, is all at once seized with symptoms of peritonitis, which runs its course in a very short time, we make the diagnosis of perforation of the intestines. That this diagnosis

is applicable to a vast majority of cases will appear when I tell you, that in ten cases where I have given such an opinion it has been verified afterwards by dissection. The rule is this, that the diagnosis before mentioned is applicable to a great many cases, and will frequently be found to prove correct. There is, however, no universal rule in medicine, we meet with exceptions, and sometimes cases come under our notice, in which perforation of the intestines, and escape of matter into the peritoneal sac, are not ushered in by any of those alarming symptoms, and there is nothing to lead you to suspect the lesion until it is revealed by post mortem examination. Andral mentions a case of a patient in whom this occurred in a very latent and insidious manner. The patient had at first a discharge of lumbrici from the umbilicus, and afterwards of matter, evidently the contents of the intestines; on dissection a great quantity of worms and matter were found in the peritoneal sac, and yet this person had only the low symptoms which characterise the chronic form of the disease. Louis gives another case. He had in this hospital a girl, in whose intestines no less than five perforations were discovered after death, and yet during life she exhibited no symptoms, except tenderness of the epigastrium. There was, however, something to account for this, for she had violent inflammation of both lungs with tubercles, and it is a law in pathology, that when one disease exists in a state of great intensity, it masks the symptoms and phenomena of another.

In cases of intestinal perforation, the progress of the disease to a fatal termination is generally very rapid, and the patient often dies in twenty-four hours or less. Yet there was one case in this hospital, in which the patient lived five days after symptoms of perforation appeared.

You will remember, gentlemen, that in the case which we have lately had under our care we took away no blood, but gave a grain of opium every second hour and some wine. Let me draw your attention to the principles of this treatment. In the first place, I must remark, that the ordinary treatment of peritonitis has been found unsuccessful in such cases. Where it has been employed the patients have invariably sunk under it, and you will easily understand the reason. Though the disease has lasted but for a few hours, pathology informs us that we have symptoms to deal with, such as would be the consequence of a long course of disease, or, in other words, that the patient will in a few hours be in the last stage of peritonitis. Another reason is this, that as long as the fistula remains open matter will be poured out, and although you may be able to modify the existing inflammation, yet the continued escape of the fecal matter will keep it up. The principles of treatment are, therefore, twofold; first, to endeavour to support your patient's strength, and in the next place, to prevent, as far as possible, the peristaltic

motion of the intestines, which keeps up the disease. The opium treatment is, then, the best you can have recourse to. It was first employed, in these perforative cases, by myself, but I must state, that the idea of exhibiting it in cases of low peritonitis, where we cannot bleed, is not original with me, all the credit of it is due to Dr. Graves, who first suggested it. It was he who first drew the attention of the medical world to those cases of peritonitis in which you cannot employ the lancet, and where opium holds out the only prospect of cure. I believe that opium possesses extraordinary power in the cure of the low form of peritonitis. In Dr. Gooch's work on Female Diseases, and in Dr. Cusack's paper on Low Peritonitis, you will find many instances of the unequivocal value of opium. Eleven years ago a woman, who was in this hospital, labouring under dropsy, had a violent attack of peritonitis coming on, after the operation for paracentesis had been performed. The woman was low, weak, and exhausted, it was impossible to take away blood by venesection; and, at a consultation held on the case, leeches to the abdomen were proposed. To this Dr. Graves would not consent, because he thought it would only precipitate a fatal termination. He gave a full dose of opium to relieve the vomiting, and the woman fell asleep. After some hours she awoke much better; he repeated the dose, and there was still further improvement, and, by a continuance of the same treatment, the woman, to the astonishment of all, recovered. Subsequently, there was a case of a woman who had hepatic abscess in the hospital. The operation for giving exit to the pus was performed unsuccessfully; the matter, instead of coming through the wound, found its way into the peritoneum, and the patient got a sudden attack of peritonitis. There was neither blood drawn nor leeches applied; the woman had full doses of opium given; blisters were used, and a generous diet, with wine and porter, employed. She recovered from the peritonitis, though she afterwards sunk under the hepatic abscess, which was very extensive. We opened the body, and found that the diagnosis was correct. From these and other cases we were induced to think that opium possessed some power in arresting this form of peritonitis; and, connecting this circumstance with the acknowledged influence it has in checking the peristaltic motions of the intestines, it was determined to give it a fair trial. Some time afterwards, Mr. Pakenham, who was then apothecary to this hospital, was called to visit a boy, who, after having had diarrhoea for a few days, was suddenly attacked with this low kind of peritonitis. He was in a very alarming state when Mr. Pakenham saw him, who recommended him to come into the hospital. I visited him a short time after his admission, and made the diagnosis of peritonitis from perforation of some part of the intestinal tube. His condition appeared almost desperate; his

pulse was rapid, small, and thready; his face hippocratic, and his extremities cold. We determined to try what opium could do for him, and administered it in full doses. Next morning he began to feel warm, and said he was something better. We continued the treatment for two days longer, and at the expiration of this time I can assure you all his dangerous symptoms had completely vanished. His belly was soft and free from pain, his look tranquil, his pulse full and slow; in fact, he said he was well. Under these circumstances, I thought I might safely discontinue the opium; and as he suffered some inconvenience from confinement of bowels, I gave him a small dose of Rochelle salts. Shortly after taking this he passed three or four liquid stools; the symptoms of peritoneal inflammation came on again with increased violence, and the boy died. On dissection, we found an open perforation in the cæcum. In this instance, gentlemen, you may perceive that I lost my patient from a prejudice of my early education—a fear of letting him remain too long with costive bowels. Had I waited until the effused lymph had been properly and perfectly organised I think he would have recovered. This case is an important and remarkable one; it illustrates the efficacy and value of opium in peritonitis from perforation, and the danger which attends any thing capable of exciting the peristaltic motion of the intestines.

The next case which came under my notice was that of a patient who took a very large dose of Glauber's salts, and got hypercatharsis in consequence. This individual was afterwards suddenly seized with symptoms of peritonitis, for which he was admitted into the hospital. Opium was given in full and repeated doses;—in twenty-four hours he took twenty-four grains. One hundred and eighty-four grains were taken before he recovered, and yet, I must tell you, there was not the slightest narcotism. In this case, you may be sure, I did not venture to give any purgative until the man had been for a considerable time out of danger. You will perceive, therefore, gentlemen, that you should not, in such cases, totally despair of your patient's recovery, particularly if you have been able to give opium at an early stage of the disease. It is a very singular thing, that patients in this state will bear extraordinary doses of opium; you will be surprised at the quantity which may be taken without producing narcotism. It is also remarkable, that one of the best and most favourable signs is the circumstance of your patient bearing the opium well. Where the opium is not easily borne, and disagrees with the patient, our prognosis is generally unfavourable, so that you see the tolerance of opium is to be regarded as an auspicious symptom. In addition to this, it will be essentially necessary to support your patient's strength by a nutritious diet. On this subject a remark has been made by Mr. Chute, which is of considerable importance, namely, that you

should be very careful not to give any nutriment in the fluid form, particularly where we have reason to suspect that the perforation is in the stomach. In such a case, if food be given in the fluid state it will immediately pass through the fistulous opening and aggravate the original mischief. Under these circumstances, I would advise you to give as little fluid as possible; give enemata of nutritious broths as often as you like, but do not let any fluid enter the stomach. Where the perforation is in the small intestines there is not so much danger, as the fluid may be absorbed before it reaches the opening, and thus be prevented from doing any harm. It is astonishing to think how rapidly and sedulously nature works in such cases;—lymph is poured out and false membranes formed in an incredibly short space of time. In a case of peritonitis which followed the effusion of a portion of the contents of an hepatic abscess into the peritoneal sac, we have found the false membranes perfectly organised in the space of a few days. In Andral's Pathological Anatomy you will find a great many very striking examples of the rapid organisation of lymph under similar circumstances.

There is another point connected with the prognosis of peritonitis from effusion of the contents of some part of the intestinal tube, which is, the size of the opening. The smaller the perforation is the greater is the chance of nature filling up the aperture and accomplishing a cure. Hence it is, that, in case of rupture of the intestines from external violence, which is generally found to be very extensive, the advantages held out by the opium treatment are less certain, and the prospect of recovery more doubtful. It has been tried in many cases of this kind in Stephen's Hospital, and in every instance except one has failed. Where the opening is very large, and a vast quantity of the contents of the intestinal tube is thrown into the peritoneal sac, the danger is proportionably increased, and the hopes of relief extremely small.

There is a case, gentlemen, in one of the upper wards on which I shall make a few remarks. It is a case of fractured ribs, which has been lately admitted into the hospital, and exhibits the great value of percussion in disease of the chest coming on after broken ribs. The patient got a fall, in which two of his ribs were broken; and he laboured under pain in the affected side, difficulty of breathing, and short dry cough, for several days before we saw him. The question is, then, has he pleuritic effusion? I think you can satisfy yourselves on this point by carefully percussing the chest. If it sounds clear on percussion there has been no pleuritis, or if there has, it is of a dry kind, and there is no effusion of fluid. In such a case as this you cannot make a satisfactory examination with the stethoscope; the man will not dilate the affected side in consequence of the pain which it gives him. But, by percussion, you can ascertain

what is the state of the pleura, and know whether there is liquid effusion or not.

In the same ward there is another important case,—it is one of pericarditis combined with abdominal disease. This is the fourth instance of this disease which I have seen since I commenced attending the hospital wards, in which we have been enabled to make a diagnosis from the friction of the opposed surfaces of the pericardium, which are made rough by the effusion of coagulable lymph. In the three former cases we could trace the disease from its commencement, as the patients had been for some time in the hospital before it came on. In the present instance we had not this advantage, as the patient had the pericarditis at the time of his admission. I shall not dwell any longer on this case, as we have not come to any decided opinion respecting it; but my impression at present is, that there is an effusion of lymph on the opposed surfaces of the pericardium; a few days, however, will enable us to form a correct opinion.

There is one remarkable circumstance connected with every one of these cases, namely, that in none of them have we been able to observe one of the symptoms which are given as peculiar to the disease—irregularity of pulse. Neither did the patients complain of pain in the region of the heart; however, when closely questioned on the subject, they said they felt some pain in that region, but did not make it a subject of general remark. How far this may arise from the effusion of lymph or of purulent matter I do not know; it is, nevertheless, a very curious circumstance.

Gentlemen, it is my intention to devote the remainder of our present course to the consideration of *fever*, and to draw your attention in particular to the doctrines of M. Broussais, as I believe the views of that pathologist on the subject of fever are not well understood in this country. This subject involves many and important considerations, and I hope to be able to give you a brief and satisfactory exposition of his opinions, and to show you where his conclusions have been well grounded and where he has passed the bounds of truth; and fallen into those errors which have caused his doctrines to be received with mistrust and suspicion.

CLINICAL LECTURES,

DELIVERED AT THE

HOTEL DIEU, IN PARIS,

During the Session of 1832–33.

BY BARON DUPUYTREN,

PRINCIPAL SURGEON OF THAT HOSPITAL.

Corrected by himself.

WE will now cite some observations in support of the statements that have been advanced.

FIRST CASE.—Inguinal Hernia.—Strangulated by the neck of the Sac.—Operation.

—*Peritonitis.—Death.*—A man, aged forty, short in stature, and of a generally good constitution, came to the Hotel Dieu with a strangulated hernia.

He had been troubled with a tumour on the right groin for the last four or five years. He dated the origin of it to carrying a sack of flour which was divided into two portions, the anterior one, which was the heavier, having thrown him forwards, he made a violent movement backward, in order to arrest his fall, and was immediately seized with a severe pain on the left side of the chest, from the distension of the muscles. This pain grew better, but some time afterwards a small tumour showed itself in the right groin, which disappeared upon his lying down, and again showed itself when he stood up, and a tumour similar in all respects showed itself on the other side. These were two inguinal herniæ, the former was larger than the latter. He used a double inguinal bandage, and by this means he preserved himself safe from any untoward accident. In removing it, however, to void his urine, owing to the expulsive action of the muscles in this effort, the tumour of the right side became larger than usual, hard, incarcerated, and immovable. From this time the patient began to experience colicky pains, nausea, and vomitings, with obstinate constipation. Some useless attempts at reduction took place. Whilst these efforts were being made, M. Dupuytren stated that the strangulation was at the neck of the hernial sac. The patient was placed in the bath, the taxis was again applied, but without any better success. It would not do now, said the Professor, to wait till the hernia became reduced of itself, for if such a wished-for termination occurs under some circumstances, how often do not peritonitis, gangrene, and death occur from an operation too long deferred. It has been frequently remarked that the greater number of cures after operations have been in those in whom the operations have been performed within the first twelve hours after strangulation, than in those in whom it has not been performed. Besides which, the strangulation at the neck of the sac becomes a strong reason why the operation should be quickly performed, it being well known that in instances of this nature, out of ten cases it is scarcely possible to reduce one. The soft state of the tumour no doubt influences this very much, but in this case the tumour was hard and stretched.

The operation was thus performed. The skin covering the superior part of the tumour was lifted up, and disposed in folds, and an incision made through them by a bistoury, which was extended to the superior portion of the tumour, that the ring might be freely exposed, and carried to the inferior portion of the tumour to avoid the formation of a sac. A small artery was divided, which was secured by a ligature. The hernial sac was found to contain fluid, which upon its being opened

escaped in considerable quantity, and the portion of the strangulated intestine was found of a deep red, and over some parts of it this appearance was so apparent as to lead to the supposition that the efforts of reduction had been made with some violence; this redness was found to extend along some portion of the intestine into the abdomen. The finger being introduced into the wound justified the accuracy of M. Dupuytren's diagnosis, the neck of the hernial sac was divided above, and in the median line, and the strangulated portion was immediately returned, and the wound dressed.

A lavement was administered immediately after the operation, which operated freely. On the ensuing day the abdomen became painful, he took some infusion of chamomile, which expelled a large body of flatus, from which he felt relieved. On the fourth day after the operation he was doing well. The wound looked healthy, and the sub-peritoneal cellular tissue looked slightly tumefied. He was ordered mucilaginous anodyne drinks.

On the fifth day he was suddenly seized with delirium, without either heat or fever. An anodyne potion was given him. The delirious affection being of a nervous nature, M. Dupuytren prescribed him twelve drops of laudanum. The cerebral symptoms soon disappeared, and in seven days there was no trace of them left. On the nineteenth day after the operation, on examining the wound, which appeared healing kindly, a hard, resisting tumour was felt above the iliac fossa, in the centre of which slight fluctuation could be detected. This tumour could scarcely be an abscess filled with stercoraceous matter, as the hernia had been only strangulated for twelve hours before it was reduced. There was reason to suppose it might be inflammation developed in the cellular tissue surrounding the neck of the sac, and which had thence spread to the tegumentary substance of the abdominal parietes. If left to itself effusion might come on. If situated in the abdomen and opened before adhesions could take place, fatal effusion might occur. In many cases M. Dupuytren has seen such abscesses discharge themselves by the inguinal canal, and has often favoured such a discharge by introducing a female sound as far as the seat of the abscess. He therefore treated this case in a like manner, but he could not reach the abscess with either a female sound or a stillette, and he therefore determined to leave the case to the natural efforts of the constitution. By gradual degrees the suppuration approached the skin, and when the adhesions were considered to be sufficient to prevent effusion, the abscess was opened. But a small quantity of healthy pus at first flowed, but on the bistoury being plunged deeper, and the incision enlarged, a considerable flow of matter ensued, and the patient felt immediate relief, although the sub-cutaneous enlargement did not completely disappear. Some simple dressing was placed on

the wound. For two days the matter flowed pretty freely, on the fourth day he was suddenly seized towards evening with colicky pains in the abdomen, nausea, and vomitings. Leeches were applied. On visiting him these symptoms appeared somewhat subdued, but the patient's eyes were sunken, and he had a cadaverous appearance, and on the following day he died.

Autopsy.—In the right inguinal region was a cicatrix two inches in length. Nothing unusual was noticed in the head or chest. The peritoneum presented evident traces of inflammation. Slight traces of pus were found between the intestinal convolutions, which were slightly adherent to one another. A fistulous orifice was seen near the abdominal opening of the inguinal canal, situated between the peritoneum and an abscess in the abdominal parietes, and there was another perforation corresponding with the external aperture, but which was stopped up by intimate adhesions with the cæcum. The abscess appeared to have arisen in the inguinal canal, and thence to have spread to the abdominal parietes, it was bordered internally by intestinal adhesions to the abdominal parietes, and externally by the cicatrix. The adhesions appeared to have been broken down, and produced effusion through the fistulous orifice first described.

This case may furnish many important remarks; individuals affected with hernia are eager to use a bandage which they may think it possible to lay aside either to satisfy the calls of nature, or to sleep. In the first instance it frequently happens that, during an effort of expulsion, the hernia comes down and becomes strangulated; in the second instance, the same accident occurs sometimes in getting into bed, or in certain motions of the body; persons, therefore, who suffer from such affections, cannot be too strongly advised to keep on the bandage night and day. In the case before us the hernia was a large inguinal one, a considerable knuckle of intestine appeared strangulated, but the inguinal canal had no constriction on it, the strangulation existed, therefore, on the cutting edge formed by the peritoneum, where the formation of the sac first commences; the operation proved the truth of this diagnosis. Every thing betokened a happy termination, when an abscess, which often occurs in the cellular tissue around the neck of the sac, was formed, and fatal peritonitis ensued.

SECOND CASE.—*Vaginal inguinal hernia strangulated by the neck of the sac.*—Abel Formour, æt. 23, thin and of a lymphatic temperament, had ever since his infancy an inguinal hernia of the right side, which he could not support; a slight effort caused strangulation, which was accompanied by hiccough, nausea, vomitings, and colic. He made some efforts to reduce it, and forty-eight hours afterwards he came to the Hotel Dieu with the following symptoms.

The hernial tumour was about the size of a hen's egg, and admitted of partial reduction, but the moment pressure was removed, it resumed its ordinary volume, and a hardness was felt the whole length of the inguinal canal; the belly was swollen, tense, and sensible to pressure; the patient had constant bilious vomitings, accompanied with colicky pains; the pulse was contracted and frequent. He was placed in the bath, and the taxis was applied without relief. The patient refused to submit to the operation; he was frequently bled, and kept in the bath during several hours, and on the following day leeches were applied to the anus and over the belly. On the following day he had stercoraceous vomitings; pulse frequent and contracted; considerable tension of the belly, and thirst; he was directed not to drink much, that the vomitings might be allayed, and to moisten his mouth with orange juice. On the third day there was extreme pain over the abdomen; extreme prostration; general pallor; and the patient still refused to submit to the operation. On the fourth day the pulse could scarcely be felt; there was considerable weakness, and slight remission of the symptoms, and on pressing on the hernial tumour crepitation was felt all over it, showing that the parts contained in it were mortified. On the fifth day the hiccough became more severe, and the extremities were cold. On the sixth day there was constant hiccough, insensible pulse, and general coldness of the body. On the following day he wished the operation to be performed, but soon died.

Autopsy twenty-four hours after death.—The belly was somewhat less tense than during life, and there was no cadaveric stiffness. M. Dupuytren performed the operation as he would have done it on the living body. The soft parts having been divided down to the sac, it was then opened on its anterior inferior surface. Some dark liquid serum escaped, having a gangrenous smell, and a knuckle of grey intestine, from three and a half to four inches in length, was shown, having a slate coloured appearance, and of the soft consistence of moist paper. Above the intestine was seen the anterior extremity of the testicle, the finger could easily be introduced into the ring, and carried along the whole length of the inguinal canal, where the strangulation was situated, which was found to be formed of a falciformed circular neck, adhering anteriorly and posteriorly to the intestine, for the extent of about one line. Above the seat of the strangulation, the intestine was found slightly perforated from the superior end, of which mortification existed to the extent of three inches. From the point, where the mortification terminated, there was a dark redness spread over the intestine, extending to the stomach. The inferior end of the strangulated portion of the intestine, which was about six inches apart from the cæcum, was twisted upon itself, as was the whole of the great intestine, the volume of which was hardly

equal to that of a child of six years. In the superior portion was contained much liquid stercoraceous matter, which would have escaped into the cavity of the belly, by the small aperture in the intestine, if there had been no adhesion formed. On lifting up the strangulated portion a circular depression in the intestine was found, which, on being examined internally, appeared deprived of its two internal membranes. The entire portion of intestine adhered in convolutions by numerous recent adhesive formations. The lower cavity of the abdomen contained a considerable quantity of pus. On the abdomen being opened, a large quantity of serum escaped, and some foetid gas, which was inflammable. The posterior surface of the lungs was somewhat engorged; the other organs were healthy.

The escape of gas, on the abdomen being opened, confirms an important fact, viz.: that inflammation of membranous surfaces effects not only a change in the quantity but likewise in the quality of their secretions. The gas, in this case, was probably carbonated hydrogen. We have said, continued M. Dupuytren, that internal strangulations, arising from the reduction *en masse* of herniæ, which are strangulated by the neck of the sac, may be always distinguished as much from the signs, proving the anterior existence of a hernia strangulated externally, as from the actual symptoms of the case themselves; cases now and then occur which are not easily recognised, especially if the previous reduction of the hernia has not been witnessed. The uncertainty becomes greater if the patient has two herniæ, which have been both reduced together, and which offer no more discernible signs of strangulation on the one side than on the other.

THIRD CASE.—Double Inguinal Hernia.—Strangulation by the Neck.—Operation.—Dressing.—Cure.—Jacques Geoffroy, locksmith, aged 40, had two inguinal herniæ, that on the left side had existed twelve years, that on the right three years; the first had been supported by a bandage for seven or eight years, the second had been left to itself. One day, in walking, he felt the bandage give way, he put his hand on his left side, which immediately gave him great pain and increased in size. On returning home he used every means to reduce it, and had all the symptoms of strangulation. On the following day he took of his own accord an emetic, and a surgeon, whom he called in, after repeated attempts at reduction, succeeded, but he still felt all the bad effects, and on the fifth day he was brought to the Hôtel Dieu. M. Dupuytren examined him with the greatest attention; the belly was painful, he had hiccoughing, vomiting of fecal matter, and constipation; features contracted.

The signs of strangulation were present, and peritonitis was feared, and the diagnosis was otherwise difficult on account of both herniæ having been reduced, and showing no appearance of a tumour behind the inguinal

ring. There was, besides, no means of ascertaining the anterior existence of these herniæ but by the dilatation of the rings and the contradictory statements of the patient. M. Dupuytren did not wish to perform the operation without being well convinced that there was no other chance of saving the patient; but, on the following day finding him much worse, the operation was decided upon.

Having remarked the tumour situated in the right inguinal region, and that the patient there complained of the greatest pain, it was on that side that the cause of the strangulation was sought for.

An incision was made through the skin in the axis of the hernial tumour; beneath this incision was a small tumour which might have been mistaken for the spermatic cord, or for the hernial sac itself, until, upon opening it, a quantity of serum flowed out, and it was found to be a cyst, behind which was placed the true hernial sac. This, which was of small size, contained neither intestine nor epiploon, but a small quantity of serum, in which floated some albuminous flocculi. On the finger being introduced into the abdomen, intestinal adhesions were detected, either to one another, or to the abdominal parietes, forming unequivocal signs of peritonitis. The operation was then immediately performed on the other side, the cellular coverings over the tumour were incised carefully until a sac was opened containing a fatty substance, supposed to be epiploon. M. Dupuytren also believed it, but seeing beneath it some fibrous bands, he made the patient cough, which caused the tumour to be lifted up, and which was then carefully divided. A considerable quantity of sanguinolent serum immediately escaped, which, compared with the fluid exuded on the opposite side, formed a complete proof of strangulation. A large quantity of reddish coloured fat was found in the sac, which proved to be epiploon in a tumefied state. On introducing the finger in the ring, a circular bridle was felt, sufficiently high up. The sac was drawn outwards with a small portion of red elastic intestine, whilst an assistant held it forcibly and drew together the two incised edges of the sac; a blunt pointed bistoury was carried along the finger, and the bridle was divided from above outwards; the pain caused by this made the patient press outwards, which expelled a large portion of intestine, and the bridle was then divided in different directions. After dressing the wound the patient was carried to bed, and passed the rest of the day very well. Lavements of milk were administered and fomentations were applied to the lower part of the abdomen, which was painful. The face was flushed, pulse quick, and tongue brown; to be bled. On the following day the vomitings were abated, but the colicky pains were very troublesome; pulse quick, face flushed. He was repeatedly bled on this and the following day. Gradually the abdominal pains subsided, and he perfectly recovered.

A TRANSLATION OF BARON ALIBERT ON DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

(Continued from page 306.)

ARTICLE II.

Of the Organic Causes which influence the development of the Teignes.

I SHALL now relate the opinions of the ancients on the organic causes of the different kinds of teigne. Some attribute them to degenerated bile, others to bad humours, and some accuser urses or parents of a vitiated and corrupted blood; but, in a work dedicated to exact truths, we must put aside scholastic verbosity. The morbid phenomena in question are easily explained by the natural laws of life; for if the mucous teigne usually disappears when teething is over, if the other forms are, for the most part, cured at the age of puberty, on what basis can we attribute these sort of exanthemas to such origins? The observations which follow tend, I think, to clear more this physiological problem. Who, in short, is ignorant that each epoch of our existence is particularly destined to the development of certain systems of the animal economy? It is thus that nature, having reserved infancy for the perfection of the head, and the important viscus it contains, preserves for this object *the focus of an active and energetic life*. The blood circulates with more rapidity in the brain, and appears to occasion a greater flow of the fluids and nutritive moisture; besides, it is at this age that the act of dentition is performed; from thence it happens that the heat of the head is singularly increased, as the redness and inflammation of the cheeks, and increase of salivary discharge, evince. To this purely organic cause is joined the powerful influence of physical habits. Children have hardly come from their mothers' breast before their heads are carefully covered with several caps; the body is tightened with swaddling clothes, which causes increased deter-

mination to the upper parts of the body; and the intellectual phenomena, perhaps, concur, in some measure, to augment the vital action in the cerebral organs, for it is at this period that all the senses become variously exercised, that the memory develops itself, &c. It is not, therefore, surprising, that this part of the organisation is more subject than the others to morbid affections, and that consequently the changes in the scalp are most frequent. It is also this extreme susceptibility of the lymphatic system which gives cause to the hydrocephalus, and other diseases which have the same foundation. These opinions have been established by modern physiologists; among others by M. d'Etanges, who has suggested the inoculation of the mucous form as a means of prevention and cure of more formidable diseases. The idea of this practitioner is founded on the general necessity of an exanthema in the scalp at this period of life, and on the advantages which result from it in the preservation of health. M. l'Homme, who practises at Oulchy le Chateau, appears especially to have appreciated it, when he happily communicated it to a child of three years of age, and thereby cured chronic enteritis which was gradually destroying it. He dipped the end of a lancet in the ichorous fluid which flows from the mucous teigne, and inoculated with it the forehead of the child by six pricks. Better to insure the success of this experiment, he enveloped the head of the little patient every evening with a linen dipped in the same matter. Ten days after the forehead and face were covered with humid crusts. The result of this exanthema appeared in a surprising manner; the symptoms of enteritis, and the tenderness of the abdomen diminished daily; the diarrhoea decreased as the eruption showed itself, and the child, by degrees, recovered his appetite and strength. The only remains of this affection was a slight looseness, and a depraved taste for earthy substances; but, by the use of

some tonics, these symptoms disappeared.

My observations at the Hospital St. Louis have proved to me, moreover, that these kinds of inoculation might be tried with advantage. I shall relate, by and by, what I have obtained from them. I think, therefore, that the crusty or scaly matter with which the scalps of children are covered may be compared to the different gums or juices which flow from the bark of certain trees when these juices are elaborated with too considerable an organic activity, and these eruptions are almost always the result of a principle of exuberant life, to which nature furnishes an issue. The lower class of people, even, are convinced of this truth; and you often hear nurses regretting that their foster-children are deprived of these sorts of exanthemata, and using efforts to produce them. The most experienced of the faculty are of the same opinion. This remark is particularly applicable to the superficial ulcerations which constitute the mucous teigne; and they daily have recourse to stimulating topical applications, the good effects arising from which cannot be disputed. All the forms of teigne, however pernicious in their character, are always ultimately of real utility in warding off more formidable diseases, and consequently explain why the subduing of these exanthemata has been, in some cases, so fatal. Nature sometimes supplies, by other ways, these morbid deprivations. I have seen an obstinate diarrhoea succeed the spontaneous suppression of the mucous scald head. The fact which follows is worthy of remark. A young girl at the Hospital St. Louis was afflicted with the furfureous scald head. Her head was rubbed with an ointment composed of flour of sulphur and hog's lard. When the itching in the scalp diminished the patient experienced a violent itching in the genital organs, and an eruption of red pimples showed themselves; on the contrary, when the application of sulphur was dis-

continued, the itching and exanthema no longer existed, and the disease of the scalp appeared afresh. All constitutions are not equally subject to the teignes; the favous particularly attacks sanguine and bilious constitutions. I have observed this affection in black, light, and even red hair. The children most subject to the granulated form are those with a brown or tawny skin; they have generally a less florid complexion than those afflicted with the preceding form. The furfuraceous is most common to those with hair of a clear chestnut colour. The amianthous has been constantly observed in melancholy constitutions; the mucous affects children with hair of a fine gold colour. These often appear hereditary, at least if I may judge by the children at the Hospital St. Louis. I have, besides, seen several sons by the same mother attacked altogether with the same form, and which appeared even when they were separated from each other, so that it could not be said that they had caught it through contagion. We shall prove in our next article, that this means of communication is not so frequent as is generally supposed, and that many restrictions must be placed on the theory of contagion.

SOME OBSERVATIONS ON THE PECULIARITIES OF DISEASES IN INFANTS AND CHILDREN.

BY J. K. WALKER, M.D.

Bad effects from the cure of Itch. Very lately I saw a child, Mary Calverly, ætat. two years, who lay in a comatose state, the pupils dilated and insensible to light; the respiration interrupted by sighs; pulse weak and irregular; bowels costive. On inquiry, I found that the child for several months had been troubled with an eruption which the mother called the itch, which had occupied not only the arms and thighs, but other parts of the body. The eruption not giving way to the internal exhibition of alteratives, the external application of an

ointment, consisting of the *unguentum sulphuricus* with a little of the *ung. hyd. nit.* to it, was successful in producing the desired result. Since that time the child's health has been on the decline, and she has complained of great pains in the bowels and loss of appetite, succeeded by frequent evening exacerbations of fever, and grinding of the teeth during sleep, &c. Shortly after the appearance of these symptoms she complained of pain in her head which was soon followed by stupor and convulsions. At the period my attention was drawn to the case, she had been relieved by the repeated application of leeches to the head, and the continued use of calomel, to which I added the friction of the tartar-emetic ointment upon the arms and thighs, wishing to reproduce an eruption on those parts. The relief (if so it might be called) continued but for a day or two, for the stupor increased, the pulse became weaker, and general convulsions followed, terminating in death.

Coma removed by Tonics.—Case. Mary Shaw, ætat. two years, an out-patient of the Huddersfield Infirmary, lay for many weeks in a state of coma, from which it was difficult to rouse her. There was, at the same time, excessive emaciation of the entire body, produced partly by a protracted diarrhoea, and previous inadequate nutrition, so that it was considered by all as a hopeless case; and yet this child gradually recovered by the occasional use of carbonate of soda and calomel, with the aid of chalybeate drops, and under this treatment the little patient recovered from the state of stupor which wore so menacing an aspect. The diarrhoea gradually gave way, and along with an improved state of the digestive functions the appetite and strength increased, and nothing has since occurred to retard a complete return to health.

Laryngeal Spasm.—One of the last examples of this spasmodic affection, which has fallen under my

observation, occurred in an infant whose health, in other respects, did not materially suffer. The attacks of crowing inspiration returned at intervals, sometimes during the night; occasionally they were accompanied by a rigidity of the thumbs and toes, often with convulsions. At all other times the child was playful and lively. The gums were lanced, and the bowels maintained in an open state with the aid of calomel, and the occasional use of clysters medicated with assafoetida or spir. terebinth. On the supposition that, from the violence of these attacks, some cerebral affection might supervene, leeches were applied to the neck. From a steady perseverance in these remedies, no advantage was reaped beyond a temporary respite from these spasmodic shocks. They again returned, and the gums were again divided, and counter-irritation applied to the nape of the neck. At the time I was first consulted in the case, the child was slightly relieved by a tonic plan of treatment, and by the sulphas quininæ repeated in small doses. But on reading the cases narrated by Dr. Marshal Hall, where such striking benefits resulted from a change of air under similar circumstances, I had no hesitation in recommending a trial of the same plan in this case, and after a removal to Matlock, the child experienced fewer of these convulsive movements, and in a few weeks they ceased entirely, and a rapid amendment in health and strength ensued. — *Trans. Prov. Med. and Surg. Assoc.*

CASES TREATED IN THE STIRLING DISPENSARY, WITH REMARKS.

BY W. H. FORREST, SURGEON.

(Concluded from p. 308.)

Yellow Softening, or Ramollissement of the Liver.—S. M. æt. 21, who had led for some time past a very dissolute and intemperate life, was admitted with great enlargement of the liver, complicated with alarming symptoms of disease of the heart and lungs. Her skin was not at all discoloured,

her countenance was full and bloated, and she had some cedema of the feet. Throughout the whole attack her stools were fæculent and bilious. She had complained for two months only, and her friends and herself attributed her illness to a severe blow which she had received some time previously. In the course of three months and a few weeks after her admission she died, after suffering for a few days from diarrhoea. During her whole attack she lay on her right side.

Dissection.—The liver was enormously enlarged, and had degenerated throughout its whole mass into a soft yellow homogeneous substance, not unlike palm oil, but somewhat paler and firmer, it could be very easily torn with the fingers. The gall-bladder was healthy and full of bile. The heart and lungs were extensively diseased. This affection, so far as I can learn, differs from the *cirrhosis* of the French. *Cirrhosis* appears to be allied rather to induration than softening, if we may judge from its resemblance to wax, and from the appellation which it has in consequence received.

Black Softening, or Ramollissement of the Liver.—Angus Sinclair, æt. 59, was admitted, having laboured under jaundice two months previously, the symptoms of which were mild and not very well marked. He never complained of the pain in the region of the liver, and, although his pulse was occasionally full and sharp, there was nothing which indicated any thing like active disease, either in this or any other organ. The remedies employed were leeches, blisters, mercurials, and occasionally drastic purgatives. When admitted his skin was of a very deep dirty yellow, and he was emaciated to the last degree. There were no local symptoms which could be referred to the liver, such as pain, tenderness, tumefaction, or fluctuation in the right hypochondrium, and the functions of the stomach were also undisturbed. His pulse was a little more frequent than natural, and weak, and soft; his bowels were con-

stipated, and moved with very great difficulty; he stated that he never had a stool without he took medicine to produce it; that no medicine, however strong, would operate on him but sulphate of magnesia, and it required four ounces of it to produce the effects of an ordinary dose. Subsequent observation confirmed this statement. I gave him once an ounce of castor oil with three drops of croton oil in it without success; he took afterwards, of his own accord, his usual dose of salts, and it operated well. The evacuations thus procured were always serous. So far as I could observe or learn they were never discoloured, or tinged with bile. His treatment at the dispensary consisted chiefly of tonics and a liberal allowance of liquid nourishment; he took for a fortnight, by the advice of one of the consulting physicians, pills composed of calomel and scammony, but without any benefit. He died a month after his admission, completely exhausted.

Dissection.—The whole body was very much emaciated and discoloured. The liver, throughout its whole substance, had degenerated into a dark liquid, resembling treacle, but less adhesive and consistent. On dividing its peritoneal covering, this liquid escaped in great abundance. There was also an escape of a foetid gas, indicated by its odour, and by the formation of numerous and pretty large bubbles on the surface of the liquid. This liquid seemed to occupy about as much space as the liver usually does. The gall-bladder was very much collapsed and empty. All the other organs, abdominal and thoracic, appeared to be quite sound.

Tubera diffused through the Substance of the Liver.—Neil Kennedy, æt. 80, was admitted, complaining of pain in the site of the liver, which felt very much enlarged. His skin and eyes had a slight yellow tinge, and his urine was very scanty, dark, and thick; his bowels were natural, and he had no preternatural heat of

skin, thirst, or frequency of pulse. There was some effusion into the abdomen, with a slight cedema of the feet. He had led rather an intemperate life, and had suffered much from intermittent fever whilst residing in a marshy district. Three months before his admission, I saw him for violent pain extending over the whole abdomen, which yielded readily to a dose of calomel and Dover's powders, followed by a dose of castor oil. He dated his illness from the period of this attack, from which he stated he never completely recovered. The treatment, after his admission to the dispensary, consisted chiefly of diuretics and laxatives. The dropsy, notwithstanding, made very rapid progress, and he died within three weeks after his admission.

Dissection.—The liver was very much enlarged, and consisted chiefly of large oval, but somewhat irregular, tubera, most of which were hard and white like tallow; some of them were soft, and contained in their centre a fluid resembling pus. The parenchyma of the liver, in which these tubera were imbedded, appeared to be natural. The liver, viewed externally, resembled very much a large mass of conglomerated rock. There was a considerable quantity of fluid effused into the abdomen and chest.—*Glas. Med. Jour.*

Reviews.

The Cyclopædia of Practical Medicine. Part XVIII.

ANOTHER part of this work has been published: it contains fourteen articles, which, with some few exceptions, are all of the average degree of merit with those contained in former parts. We took occasion in a former number to notice Dr. Montgomery's paper on the "Signs of Pregnancy and Delivery;" its conclusion affords us the opportunity of again pronouncing it to be in all respects an able and well-written paper. The articles immediately following, on Prognosis, Pseudo-Morbid

Appearances, and Psoriasis, present but few facts worthy of particular notice, or with which the general medical reader is not already familiar. We were surprised to see the name of Dr. Marshall Hall attached to an article on Puerperal Diseases: this important class of affections on which volumes have been written is here divided into a few separate sections, and included in the short space of a dozen pages. The article Pulse is written by Dr. Bostock, in which its importance as a diagnostic of disease is traced up from the time of Hippocrates to the present day. Purpura is a condensation of the opinions of different writers on this disease, in describing the treatment of which the author sums up by quoting the practice of Dr. Belcombe, of York, who employs saline remedies in the cure of this disease. Dr. Graves, in a recently published paper in our contemporary, the "Dublin Medical Journal," states that he has found large quantities of salt food to be a frequent cause of this affection.

The remaining articles are all of proportionate degrees of merit, varying as much in terseness and vigour of style as in the relative space they occupy, or the modicum of practical (?) information they afford the reader.

The paper on Rape, by Dr. Beatty, occupies nine pages, whilst that on Pus, by Dr. Tweedie, one of the editors, is dismissed in about as many lines.—This is an editorial oversight, which at least should be corrected.

A Dictionary of Practical Medicine, comprising General Pathology, and the Nature and Treatment of Diseases, &c., &c. By JAMES COPLAND, M.D., &c., &c. Part II.

WE were the first to pronounce the most favourable opinion of the former part of the unequalled production before us, and were followed by all our contemporaries. We declared it to be the best, the most learned, and by far the most instructive work in our language. It is executed by a

gentleman of profound medical knowledge, of the most extensive research, and of great experience in the treatment of diseases both at home and abroad. Dr. Copland, with a candour that does him the greatest credit, gives the opinions of the original writers in the old and new worlds with perfect impartiality, analyses the whole, comments upon it, and modestly offers his own views in conclusion. He proves himself to be intimately acquainted with the medical literature of all countries, and like a learned compiler he lays all under contribution. He gives the substance of every writer's views in a clear, concise, and graphic manner, without in one instance destroying the author's meaning. He manifests a taste for selecting, and a power of condensing, which fall to the lot of few, while his language is elegant and classic, and free from those harsh barbarisms which are observable in other publications of a similar description. Dr. Copland takes the most comprehensive view of the practice of medicine; he gives the fullest account of the semicology, pathology, diagnosis, and treatment of diseases, deducing his conclusions from all sources; he describes the morbid lesions, or structures, the disorders incidental to climates, to the sex, and the different epochs of life, with numerous prescriptions, (we need not say chemical ones,) of the medicines recommended. He adds a classification of diseases according to pathological principles, a copious bibliography with references, and an appendix of approved formulæ, the whole forming a library of practical medicine, and a digest of medical literature. Every department of this work is executed in a masterly manner; and it will be looked upon as one of the best illustrations of the learning, science, and experience of the nineteenth century. It is absolutely an astonishing production by one individual. Every disease is most minutely described, and the latest modern opinions concerning it are faithfully given.

An Essay on Inflammation. By
PHILIP LOVEL PHILLIPS, M.D.

The subject of inflammation has long been a fruitful one with young medical authors. An affection which is so common, and at the same time so extensively universal, which assumes such Protean symptoms and appearances, and which moreover frequently baffles the most skilful and judicious treatment, would seem nevertheless to deserve more extended notice in the form of treatise or essay than it has yet received. Dr. Phillips, in the volume before us, has added his sum to the rich experience we have had of this affection; he has dwelt upon and quoted extensively from every author who has written upon the subject; his volume therefore forms a vade mecum of all previously recorded opinions and theories, and he has more particularly directed his researches "with a view to the elucidation of the proximate cause" of inflammation.

"Although physiologists and pathologists of the present day pretty generally agree in referring the proximate cause of inflammation to an altered and morbid condition of the minute blood-vessels, they are by no means so unanimous in regard to the *nature* of this alteration: in fact, the opinions which they hold upon this subject are most diametrically opposed to each other.

"There are," says Professor Thomson, "two hypotheses which divide the opinions of pathologists respecting the state of the capillary vessels affected with inflammation. According to the first, the inflamed vessels are in a state of increased action; according to the second, they act with less force than the trunks from which they are derived."

"Of course it is of great importance that we should make up our minds in favour of one or other of these opinions, as we must necessarily frame our treatment accordingly. I hope, in the following pages, to make it appear extremely *probable*, that the latter is the more correct, and that the symptoms which constitute inflammation are referable to atony of the capillary system of the part."
—p. 28.

In further elucidation of his views our author proceeds—

"Suppose we subject any part of the body to the action of excessive heat, it presently becomes redder and hotter than natural, tumid,

and painful. Now the question is, whether these symptoms are produced by the primary stimulus communicated by the heat to the vessels of the part, or by the subsequent debility induced by the primary over-excitement rendering them incapable of sustaining their usual degree of action? The latter I should conceive to be by far the most reasonable supposition; and it is considerably strengthened, if we attend to the effects produced on the nervous system generally, when subjected to the influence of intense heat; at first there is an universal excitement; but this is presently followed by a no less universal collapse, prostration of strength, and syncope. 'For all the stimulant powers may carry their energy to the degree under which no excitement will arise. The reason is, that the body becomes no longer susceptible to the operation of the stimulus, another expression for which is, that the excitability is consumed. The excitability, thus exhausted by stimulus, constitutes debility; which may be denominated indirect, because it does not arise from defect, but excess of stimulus.'

"If such are the effects of heat on the *whole* nervous system, it is but reasonable to suppose that it would act in a similar manner upon the vital powers of any *part* to which it may be applied: the consequence of this would be that the irritability of the vessels being diminished, they would no longer be able to resist the impulse communicated to the blood by the heart, or to assist in propelling it; they would, therefore, become distended, and overcharged with blood; and from this, as we shall presently see, result all the symptoms of inflammation. It is exactly upon the same principle that other positive agents produce inflammation; they first excite the vessels to increased action; then, having exhausted, they reduce them to a less degree of action than is necessary for the due performance of their functions."—pp. 32, 33.

The author quotes passages from the works of Burns, Thomson, Wilson Philip, and Hastings, in support of his views, and the toxicological observations and experiments of Orfila, Brodie, and Christison in proof of the fact that certain agents have the specific power of greatly diminishing or exhausting the irritability of the heart.

The two chapters immediately following, on the "Phenomena" and "Termination" of Inflammation, contain much valuable matter, and are well worth perusing. In speaking of the treatment of inflammation by opium, our author says,

"The use of opium in inflammation is a point upon which the greatest contrariety of

opinion exists among practitioners, but in estimating the difficulties respecting the merits of this medicine, we should bear in mind,

"1st. That where opium is exhibited in small doses to a constitution already in a state of excitement, its stimulant powers will increase that excitement; since, though weak, they tend to give a new impulse to an action already in force; whereas the succeeding sedative power will not take effect, because it is not sufficient to counteract and check the morbid activity which already exists.

"2nd. That this excitement will not be such as to benefit the inflamed part by increasing the action of its vessels; since the stimulus is general through the system, it will, of course, have the least effect upon any part the powers of which are impaired; and consequently the increased action of the system, generally, will tend to oppress this part in particular, in proportion as the sum of the stimulus to the whole circulating system, '*à tergo*,' (including the heart) is to that which acts upon the inflamed vessels alone.

"3rd. That where the excitement of the system is very great, in consequence of inflammation, and the medicine is given in such large doses as that the stimulant effects should be very much exceeded by the sedative, then the benefit will be in the same proportion as the injury was in the former case, since now the action of the whole system, '*à tergo*,' (including the heart) is diminished in a greater degree than that of the vessels of any one part can be, in proportion as the whole exceeds the part.

"4th. That morphine, which is found, according to the experiments of Magendie, to be the principle in opium which possesses the greatest share of sedative property, must be a more beneficial medicine in inflammation, than when combined with narcotine, which, from the experiments of the same physiologist, appears to be possessed of the stimulating principle.

"Thus, upon the theory which I have endeavoured to support, we can satisfactorily explain points of difference, in the effects of this medicine, which otherwise appear contradictory, and, by this means, we may learn duly to appreciate its great value when judiciously employed. Above all, we must learn to discriminate between the circumstances in which its use will be extended with advantage or with injury."—pp. 108-110.

Dr. Phillips then proceeds to the consideration of mercury, local bleeding, the application of cold, heat, and stimulants, as accessories in the treatment of inflammation, illustrating each by the remarks and observations of eminent practical writers. We shall close our notice by quoting the chapter on "*Local Actions analogous to Inflammation*."

"Of these local actions blushing is, perhaps, the best example. It consists in an increased flow of blood to the cheeks, which are consequently rendered fuller, hotter, and redder than before. This is generally, and I believe correctly, adduced as an instance of the power of mental emotions over the heart's action. Under these emotions the heart acts more rapidly and more strongly, and propels the blood with increased impetus, not indeed to one part of the body alone, but to all alike; and that part which is most amply supplied with minute blood-vessels at the surface, most readily admits an increased quantity of blood; and if the skin be also thinner there, it is more easily seen through it, as is the case with the cheeks. That the determination of blood to the surface, on such occasions, is not confined to the cheeks, is very evident in a fair-complexioned person, whose whole face, neck, and chest, become red at the same time; and we know, that when a person is violently agitated in his mind, perspiration issues from the whole surface of the body.

"The cause then of blushing is an increased action of the heart; the vessels of the cheek are passive, and as soon as the heart regains its wonted composure, the suffusion of the cheeks subsides. Mr. Mayo, in his work on Physiology, says—'We may presume that an artery, at the average tone of arteries, would be affected in the same manner by an unusually forcible contraction of the left ventricle, as a relaxed artery under the ordinary pressure of the blood.' No one, I think, will doubt this, for it is the same as if we have a spring whose force is equal to ten pounds, and a resistance equal to eight pounds, evidently the same effect will be produced if we increase the force of the spring to twelve pounds, or diminish that of the resistance to six pounds. 'The former case,' continues Mr. Mayo, 'is easily explained. The carotid artery laid bare in the neck of an ass, lies without apparent change when the animal becomes composed. But if the animal becomes alarmed, as by holding its nostrils for a few seconds, the heart acts violently, and the carotid artery leaps from its place, and becomes elongated and tortuous at each stroke of the ventricle. It follows, that if the coats of the same vessel were especially relaxed, a like phenomenon would ensue during the ordinary action of the heart.' The distension of the vessels of the cheek in blushing takes place, I conceive, in the same way as that of the carotid in the experiment; and if we grant that the minute vessels of an injured part are relaxed, then we can easily see how they will come to be distended and overloaded with blood under the ordinary action of the heart. Mr. Mayo remarks in another paragraph—'The opinion that the flow of blood in increased quantity to a part results from the relaxation of the small arteries, is remarkably confirmed by what is noticed respecting the larger vessels, wherever local action frequently

occurs, or happens to exist for a considerable period. The arteries of such parts become elongated and tortuous. This is the character of the arteries of the testes, of the uterus, of the mammae towards the latter period of utero-gestation, of the face and temples.'—pp. 126, 127.

It is very plain that in quoting these paragraphs from Mr. Mayo's work, Dr. Phillips has pressed Mr. Mayo's theory into a service for which it was never intended; so palpable indeed is this fact, that Dr. Phillips has been forced to acknowledge the plagiarism; he might have been equally charitable with the other quotations which abound through the volume. We have extracted them more because they serve well to illustrate a certain theory of inflammation, than as appertaining to any new views which the author may have thrown upon an affection on which he has professed to theorise.

A Treatise on Physiology applied to Pathology. By F. J. V. BROUSSAIS, M.D., &c. Translated from the French, by J. BELL, M.D., and R. LA ROCHE, M.D. Third American Edition, with Notes and a copious Appendix. 8vo. pp. 666.

Our transatlantic brethren are certainly before us in their translations of the French, German, and Italian works, and we can scarcely account for this, unless it is to be ascribed to the disinclination of English publishers to undertake translations. This feeling, which is a bad one, is entertained by a great majority of the London publishers. They seem to forget that the works of Richerand, Magendie, Blumenbach, Bourdelocque, Laennec, Cloquet, Andral, and many others have been most favourably received by the medical profession, and are justly considered standard productions. Nevertheless almost all proposals made to our London publishers to bring out translations of foreign works are declined. A few, and but very few, have lately appeared, while the American publishers are constantly bringing out

such works as we allude to. We are also compelled by truth to acknowledge that there is not that taste for foreign literature evinced by a preponderating majority of our brethren at home which ought to be displayed, and ought to characterise true votaries of science. Our professors and lecturers, together with our hospital medical officers, form an exception to our charge; but they are very few in number compared to the whole profession. But we have been repeatedly requested to state in this Journal, whether there were translations of many foreign works; which proves that our brethren are desirous of becoming acquainted with the state of science in other parts of the world. We must, however, cease this digression, and return to the work before us.

It has fallen to the lot of few physicians now living to arrive at such high celebrity as M. Broussais. His original doctrines of disease were at one time very generally received in his native country and in other nations; but they are now very much disputed, and we might say with truth, nearly discarded, at least in this country. His ascribing fevers and other diseases to gastro-enteritis, has very few advocates, at present, in Great Britain or any other parts of the world. But the work before us, and that on chronic diseases, must be admitted by all versed in physiology and pathology, as among the very best that modern times have produced. The application of physiology to pathology, on sound principles, is the basis of the practice of medicine. But this work must not be mistaken for the Principles of Physiological Medicine, embracing Physiology, Pathology, and Therapeutics, translated by Drs. Hay and Griffith*.

In a well-written preface the translators occupy thirty pages, in describing the progress of physiology since the time of the illustrious Haller; and then the work com-

* We take this opportunity to inform the translators that this work has not reached us.

mences with a description of man, the composition of the human body, the vital properties of tissues, vital power and laws, the external senses, encephalon and spinal prolongation; sensations, instinct, operations of the intellectual faculties, passions, laughter, ennui, sleep; the manner in which the exercise of the intellectual faculties and the passions cause disease; the muscular, nervous, absorbent, circulatory, reparatory, secretory, exhalant, nutritive, and generative functions, with an account of the various ages, temperaments, and habits.

It would be as difficult to review this systematic work, and extract from it, as to attempt to analyse a dictionary; and we therefore can only express our opinion of its worth. It is a system of physiology applied to pathology, uncommonly well executed by its author, and accurately translated by those who have undertaken to prepare an English version of it. It will be perused with delight by medical practitioners, and with interest by the general reader.

THE

London Medical & Surgical Journal

Saturday, October 12, 1833.

THE ALDERSGATE STREET DISPENSARY.

AFTER our last number went to press, we observed an advertisement in the newspapers, in which the Committee of the General Dispensary, Aldersgate-street, asserted, that the medical officers had deserted the poor, and had promised to attend their own patients only; and next followed a vote of thanks to the physicians and surgeons, who, at the request of the Committee, had attended the new patients at the Institution since the retirement of the physicians and sur-

geons. Admitting the first charge against the late medical officers, of having made no offer to prescribe for the new patients, we must contend that they were perfectly consistent in so doing. It must be obvious, that as the Governors pursued a line of conduct, which every man endowed with a particle of common sense will admit to be most injurious to the interests of the Dispensary, and degrading to the medical profession, against the unanimous opinion of those most competent to judge, and that the result led the physicians and surgeons to resign, they were perfectly justified in leaving the governors to fill up the vacant appointments agreeably to their new-fangled law, which enabled any wealthy novice in medicine to buy himself into their establishment. It would be as reasonable to argue, that after the dissolution of a partnership in a large commercial establishment, that those who retired ought to manage a share of the business until their successors were appointed. The medical officers retired in disgust at the corrupt decision of the Governors; and yet it has been urged, that they neglected the poor by declining to attend at the Dispensary. If the Governors decision were right and sensible they could have no difficulty in electing a new Medical Staff. But their charge is unreasonable and ridiculous.

With regard to their vote of thanks to the physicians and surgeons, who, contrary to the general feeling of the profession, sneaked into the Institution with the hopes, no doubt, of being

ultimately elected, we think we need not comment, and we can scarcely trust ourselves to animadvert on the lauded individuals. We are not, however, surprised, that persons were to be found in a large community like our profession, who would grasp at place, because there are some black sheep in all professions, and in all classes of society. Experience will teach such individuals, that conduct disapproved of by the body to which they belong will do them no good, either with the profession or the public. They will learn, by the result of the meeting of the medical profession, to be held on Saturday, that a preponderating majority of their brethren will denounce the nefarious system they have supported. The sale of medical appointments in public charities is murderous to the poor, and highly detrimental to the science of medicine. It enables incompetent and inexperienced medical men, who possess wealth, to throw those of talents, erudition, and experience into the shade. It deprives the unfortunate poor of the best advice, and thereby renders their condition much worse than before, while it shuts the door against the genuine cultivators of the healing art, whose industry and acquirements may be infinitely superior to those of their rivals, but whose pecuniary means may be limited and inadequate for a contest with their affluent and incompetent opponents. The pretended sympathy for the poor, urged by the Governors in the charge already noticed, very badly accords with their humane legislation;

that any tyro may buy himself into the office of medical adviser to the patients who seek aid at their institution.

We are delighted to perceive, however, that the committee, whose conduct has given rise to these strictures, are about to be brought to account "for causes which led to the resignations of His Royal Highness the Duke of Sussex, as Patron of the Dispensary, and also of the late medical officers." A meeting of the subscribers is to be held on Monday next; for this purpose, and we do not entertain a shadow of doubt, but the bribery law will be repealed, the committee censured, directly or indirectly, and the late medical officers requested to return. There is no doubt, however, but the committee will pack the meeting, as in all similar instances; and therefore every medical practitioner, who is acquainted with a single subscriber, ought to explain to him the question at issue, and entreat him to attend the meeting, and vote as reason, justice, and humanity will prompt him, for the abolition of the law, which every honest enlightened mind must condemn, as injurious to the diseased poor and our noble profession.

MEETING OF THE MEDICAL PROFESSION TO PASS A VOTE OF THANKS TO THE LATE MEDICAL OFFICERS OF THE ALDERSGATE STREET DISPENSARY.

A MEETING of the medical profession will be held on Saturday the 12th inst., at the Freemasons' Tavern, Great Queen-street, Lincoln's-Inn

Fields, at seven o'clock in the evening, DR. ELLIOTSON, F.R.S., Professor of Medicine in the London University, in the Chair.

The object of the meeting is to return a vote of thanks to Dr. Birkbeck, Dr. Clutterbuck, Dr. Lambe, Dr. Roberts, Mr. Salmon, and Mr. Coulson, the late physicians and surgeons to the General Dispensary, Aldersgate-street, for having resigned in consequence of the law proposed by the Committee and adopted by the Governors,—“ That all subscribers of seven days' standing, instead of six months, were qualified to vote at the election of medical officers.” We have already shown the bad effects of this legislation, and these are happily described by the above gentlemen in a few words. “ We left the Institution rather than countenance a system which must lead to the election of ill-educated, or otherwise improper, persons, to appointments which should be filled from professional competency alone.”

These are the sentiments of almost all the profession, with the exception of about half-a-dozen of its members ; and we therefore call upon our brethren to come forward at the meeting of this evening, and support, as they have ever done, the interests of their poor afflicted fellow-creatures, as well as the respectability of the profession to which they belong. The true interests of the zealous cultivators of medical science require that every member will do his duty. The time has arrived when medical practitioners are called upon to maintain their

rights, to protect their more competent and less affluent fellow-members, and to secure to public charities the blessings of sound medical knowledge.

POWER OF GRANTING MEDICAL DEGREES IN LONDON.

WE stated in our last that Professor Grant mentioned in his introductory lecture that the Government had determined to give the University of London the power of granting degrees in medicine. We had our information from a gentleman who was present at the lecture. A contemporary famed for politeness and good breeding, denied the accuracy of this statement, as he had received the Professor's manuscript of the lecture, and adds, ‘ now the truth is, that Dr. Grant did not make any such statement, and that if he had, it would have been contrary to the fact.’ Now unfortunately for the veracity of this assertion, our informant corroborates his statement by referring us to the notice of the lecture in the Morning Herald, by which it appears, that Dr. Grant did make the declaration, that London should have equal powers, as regards medicine, with Oxford and Cambridge, where there were no medical schools ; and 'tis passing strange if the Doctor were mis-reported, which we do not believe, he did not correct the mistake in the Herald. The sentiments delivered in a lecture, and those sent to a journal for publication, very often differ ; but as Professor Grant forwarded his lecture to our contemporary—who in the very same

number of the journal in which it appears, ridicules the pretensions of the school, "the Gower Street School," to which he belongs, and also, we believe to another contemporary, as the reports are verbatim, but forgot to favour us with a copy.—we cannot for a moment question the authenticity of the statement we made last week. We certainly admire the condescension of any lecturer or teacher "not professor," at the London University, or rather "the Gower Street School," in sending his MS., for so it was advertised in the newspapers, to a paltry, stupid, unprincipled publication, which repeatedly maligned and insulted some of the ablest lecturers in the institution to which he belongs; and so far as the impotent malice of the grandmamma who conducts it could suggest has made every effort to injure an establishment, whose professors far surpass, in point of fame and writing, those of any other institution in London. Every one of them is known by his standard work, while his pitiful reviler has not had brains enough to produce a sixpenny pamphlet as an original work. We have ever defended the University Professors on the grounds of justice only; and were they connected with any other institution would do so with equal pleasure. We care not a "bawbee," whether we receive the MS. of any of their introductory lectures; we are not driven to shifts for materials to fill our pages; nor would we be so mean as to publish the lectures of any of them, taken by an unprofessional re-

porter, contrary to his wishes, and at the same time deprecate the man whose opinions were the only props of our existence. We are not worshippers of the College of Physicians, we have no ambition to be dubbed Fellow, and wear a scarlet gown and fool's cap, nor have we lauded the lecturers of King's College because most of them were the nominee Fellows of the perpetual President of the Physicians' College, as we detest and abhor such a line of conduct. We should not be so narrow-minded as to prevent a Lecturer from furnishing the MS. of his Introductory Lecture to a contemporary, had he, like ourselves, employed a special reporter for the purpose, both reports being equally inferior to the original, a copy of which was freely promised to both. But we may meet again at Philippi; nor shall we forget in the mean time the chivalrous motto of Scotland, "*nemo me impune lacessit.*"

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Abscess of the Liver pointing externally.—D. Clarke, æt. 60, complains of a tumour in the region of the liver, which began four months ago, Mr. Stanley considered it an abscess, and deemed it advisable to open it. An incision was made, and four pints of pus mixed with hydatids were discharged. A poultice was applied, and the bowels attended to. Mr. S. observed, that this was an uncommon case, and he entertained strong hopes of the patient's recovery.

Fracture of the Patella, occasioned by the excessive Action of the Mus-

cles of the Leg during an Epileptic Fit.—Daniel Thorpe, a robust man, æt. 45, was brought to the hospital some weeks ago, his patella having been fractured while in a violent epileptic fit, by excessive action of the surrounding muscles. Since his admission he has had several fits, and has been in a state closely bordering on delirium tremens. Cathartics and stimulants were exhibited with the best effects. The fracture of the patella was evident from the depression between the two portions of the bone into which the fingers might readily be introduced. The power of extending the limb was entirely lost. It was extended on a padded splint, and the patient placed in a sitting posture, in order that the rectus muscle might be relaxed; the heel was then elevated towards the trunk of the body to approximate the lower to the upper portion of the patella, and rollers and bandages were applied. The fracture is going on favourably.

Syphilis affecting the Nose.—There is an interesting case of syphilitic ulceration of the bridge of the nose at present in the venereal ward; the patient is a young man, ætat. 25, and has been affected with syphilis for the last four years. A short time since a deep ulcer formed on the bridge of the nose, which is likely to produce permanent deformity of that feature. There is a hard swelling on the back of the hand resulting from periosteal inflammation of the bones. He has been rubbing in mercury for some time past, and is now put on sarsaparilla. Fumigations have been ordered to be used.

Rupture of the Eyeball.—Thomas Harris, a carpenter, æt. 52, was admitted into the hospital. He stated, that a short time before his admission his foot suddenly slipped, and his eye came in contact with the muzzle of a gun which he had in his hand. This was followed by a discharge of a thin fluid from the eye. On examination,

it appeared that the external tunics were torn; the eyelids were exceedingly swollen, and the ball of the eye somewhat collapsed. On the evening of his admission twenty ounces of blood were taken, and syncope supervened. Two dozen leeches were applied around the eye, and afterwards the saturnine lotion. He was ordered

Hydrar. submur. gr. vj.

Pulv. Jalap, gr. x.—Capiat statim.

The compound senna draught was also prescribed.

On the ensuing day the patient still complained of darting pains in the eyeball. Leeches were again applied, and the patient was placed in a warm bath. In a few days he became free from pain. His bowels were regular, and his general health was good, but the swelling of the eyelids, however, was not diminished. He said he felt some fluid coming out of his eye. Vision has been completely lost in the injured organ.

Abscess in Perineo.—A healthy-looking man, æt. 45, came to the hospital some days ago, complaining of a throbbing pain in the perineum, which on examination was found to result from the formation of an abscess. The tumour was of a slight yellowish colour, and a fluctuation might easily be discovered on pressure with the fingers. The patient received an injury in the part some time ago.

Constant applications of leeches were used at first, but poultices were now applied to the abscess, which was opened, and the patient is recovering.

ST. GEORGE'S HOSPITAL.

Amputation of the two external toes in a case of six toes of the right foot.—On Thursday, Oct. 3, Mr. Hawkins performed amputation of the two small toes of the right foot in a young woman, ætat. 30. The patient was born with six toes on the right foot, and has suffered considerable inconvenience from the super-

numery toe preventing her from wearing shoes. So great was the inconvenience resulting from this deformity, that she consented most willingly not only to lose the supernumerary toe, but also the toe next to it, as Mr. Hawkins deemed it advisable to include both in the operation. Mr. H. first made two semilunar incisions, one on each side of the toes, and having cut down to the metatarsal bone, quickly removed the toes by means of a small saw (used on these occasions). A few arteries (the branches of the digital and plantaris) were tied; slips of adhesive plaster were then applied, and the patient was removed to bed.

Reproduction of bone in case of amputated arm.—Operation.—On the same day another operation was performed by Mr. Hawkins.

Previous to the operation Mr. H. observed to the class, "This, gentlemen, is a case which you will often find in hospital practice; the arm in this lad was amputated in infancy, but you perceive there has been an unnatural growth of the bone, which has been prolonged through the integuments of the stump. The pain and inconvenience resulting from this prolongation of bone imperatively demand an operation."

Mr. Hawkins then passed the knife round the skin surrounding the prolonged bone, a retractor was then applied, and in a few strokes of the saw the bone was removed; several arteries were taken up. The patient struggled dreadfully during the operation, and it was with the greatest difficulty that it could be proceeded with.

Syphilitic lichen.—There is a case of syphilitic lichen at present in the hospital, with respect to which Mr. Brodie observed: "This boy had originally a sore on the penis, and was put on a course of mercury, which disagreed very much with him, and had to be abandoned. He has now two distinct kinds of eruption

on him, viz. common *itch* or scabies, and lichen, which is one of the mildest species of syphilitic eruptions. The itch is almost cured by means of sulphur. He has been put on sarsaparilla. I intend now putting him again on mercury, as I am convinced that the mercury having formerly disagreed with him was owing to his being half starved!"

MIDDLESEX HOSPITAL.

Ligature of the common Iliac Artery.—In a former number we gave the case of — Dyer, a patient in this hospital, under the care of Mr. Mayo. Our report brought the case up to the 10th.

During the few days immediately following, the patient's general condition improved very much, and the wound filled with healthy florid granulations.

13th. Slight diarrhoea, which was checked by the *Haustus Cretæ c. Opio*.

15th. In putting on his shirt, the patient used some slight bodily exertion, and soon after (about half-past eleven), it was discovered that the dressings of the wound were saturated with blood. At 12, A. M., Mr. Mayo saw him; the dressings were removed; four or five ounces of blood appeared to have been lost; the hæmorrhage had stopped; a thin strip of clot adhering to the ligature appeared to extend to the bottom of the wound, which looked healthy. Up to 11, P. M. there had been no return of the hæmorrhage, which, however, again recurred at half-past 12, P. M., when about a pint of blood was lost, but it was repressed by the application of additional compresses over the wound. Mr. Mayo, having been sent for, removed the dressings, and found the wound filled by a large mass of coagulated blood. On removing this the wound filled immediately with arterial blood. Guided by the ligature Mr. Mayo passed his finger to the bottom of the wound where the artery had been tied, and by compressing the vessel above

the ligature, arrested all further hæmorrhage, and was thus enabled to controul it whilst consulting with his colleagues as to the course necessary to be adopted.

It was decided that the common iliac should be tied for the following reasons.

1. That if the external iliac were tied *immediately above the part* which had given way, (setting aside the extreme difficulty of securing the vessel at that part,) it was to be feared that it would again give way from the same cause that it had already done so.

2. That if the external iliac was tied much *higher up*, the ligature would be applied near the origin of the *internal iliac*, and another source of secondary hæmorrhage would be thus provided.

Mr. Arnott having made pressure on the artery at the bottom of the wound, Mr. Mayo proceeded to tie the common iliac in the following manner:—An incision was made through the integuments about five inches in length, and carried upwards with a slight inclination forwards from the anterior superior spinous process of the ilium, and the muscles were divided, the peritoneum and bowels were pressed forwards, and the trunk of the common iliac artery was readily reached. A ligature was passed around it by means of a common silver aneurismal needle fixed in an ivory handle, the end of the instrument being bent to a very abrupt curve. It was tied without any difficulty. (*Our reporter made the following diagram of Mr. Mayo's incisions.*)

The case was a very difficult one, owing to the corpulence and obesity of the patient;—the vessel lay at a vertical depth of seven inches below the integumental incision.

The prognosis of the case was unfavourable, from the unhealthy character which the large frame and pale but bloated countenance of the patient presented; but the operation afforded him the best chance of preserving his life from the danger of immediate hæmorrhage. The limb was cold, but sensation in it was unimpaired. He was ordered one grain and a half of opium. He passed the night in a very restless and disturbed manner; hiccough and delirium came on; the pulse sunk, the breathing became hurried, and he died on the 16th, at 5 P. M.

Autopsy.—On examining the abdomen no morbid appearance of redness, discoloration or injury of the peritoneum was remarked, as might have been expected from its having been so extensively separated from its muscular attachments; this was accounted for by the large mass of fat situated in this region, which had served to support and protect it. The common iliac had been tied immediately above its division; the external iliac at the distance of three quarters of an inch above the origin of the epigastric. The hæmorrhage had taken place from a small ulcerated opening in the artery about a line above the ligature.

There was no general disease of the arterial system, but the femoral artery in the affected limb, near the seat of the aneurism, had some lines of ætheromatous matter interspersed between its circular fibres. The opening into the aneurismal sac was longitudinal, and one inch and a half in length. The artery in its course from the aneurism to its division at the knee-joint, was of three times its natural calibre, and filled with clotted blood.

French Medicine.

Extra Uterine Fecundation.—A female, ætat, 25, suffered from an ob-

struction of the liver. Notwithstanding medical treatment the disease progressed, and at the end of six years there was a considerable enlargement of this organ. The following year the catamenia were suppressed, the abdomen was distended, presented a manifest fluctuation, and yielded on puncture fifty pints of a limpid, serous, yellow, inodorous fluid. An examination of the abdomen after the evacuation detected nothing particular. At the expiration of twenty-two months the paracentesis was repeated, when from fifty to fifty-five pints of a purulent fluid, mixed with pieces of hair, were drawn off. An extra uterine gestation was then suspected. Six months afterwards, the operation was a third time had recourse to, when about the same quantity of a similar matter was evacuated, and a hair six inches long passed through the canula. The patient, who denied ever having had any sexual intercourse, died in about two months after the third operation. On examining the body, an immense cyst was found, filling almost the whole of the abdominal cavity, without any communication with the viscera. At the superior part of the cyst two masses of hair, covered with a fatty matter, and having the form and size of an egg, were detected; in one of these masses there was a piece of skin, a fragment of bone of eight lines long, a molar tooth, such as that of a child of five years old, and two other teeth. The anterior portion of the womb was destroyed down to its cervix, which presented nothing remarkable, and could not be penetrated by the finest probe. The remainder of the genital system was destroyed or confused with the cyst. The vulvar extremity of the vagina presented the hymen in all its natural integrity, and would scarcely admit the end of the first finger. M. Philip, the author of the account, presents this as a case of extra-uterine conception. It has been observed by the members of the Academy, that M. Philip only suspected this to be the nature of the case during the life of the patient,

on the escape of the tuft of hair during the first operation; and yet nothing is more frequent than to meet with hairy productions or of true hair in cysts, and even in those cysts formed at the expense of the ovaries, and containing serous fluid. In the second place, they only regard this as a case of monstrosity by inclusion (*monstrosité par inclusion*), analogous to those related by Baillie, Bey, Ruysch, and Dupuytren. M. Capuron adds, that the means of distinguishing extra-uterine pregnancy from this description of monstrosity is, that the placenta, which exists in the former case, is wanting in the latter example.—*Archiv. Gen.*

BOOKS.

Illustrations of the Surgical Anatomy of Inguinal and Femoral Hernia, with Mechanical Plates. By WILLIAM BLOXHAM, M.R.C.S. Folio. Two Plates. London, 1833. Highley.

This work admirably illustrates the surgical anatomy of the commonest kinds of hernia in both sexes. The plates are so constructed as to represent the different layers, or tissues, which are to be divided by the surgeon.

Syllabus of a Course of Lectures on the Principles and Practice of Surgery. By FRANK DERICK TYRRELL, Surgeon to St. Thomas's Hospital and to the London Ophthalmic Infirmary. 8vo. pp. 116. London, 1833.

This is a most comprehensive syllabus.

A Compendium of Osteology, being a Systematic Treatise on the Bones of the Human Body, designed for the Use of Students, to which is subjoined an improved Method for preparing Bones for Osteological Purposes. By GEORGE WITT, M.D., Physician to the General Infirmary, Bedford. 4to. pp. 72. London, 1833. Longman and Co.

A useful work for students.

Principles and Illustrations of Morbid Anatomy, adapted to the Elements of Andral and the Cyclopædia of Practical Medicine, with coloured drawings from Originals by the Author, with Descriptions of the Cases, Symptoms, and Treatment, &c., designed to constitute an Appendix to the Practice of Physic, and to facilitate the Study of Morbid Anatomy. By J. HOPE, M.D., F.R.S., Physician to the Mary-le-Bone Infirmary, &c. Part VII., October, 1833. Whittaker, Treacher, and Co.

This important and standard work will be finished in Five additional Numbers. It will be in every medical library.

The Treatment of Asiatic Cholera and Cholera Diarrhoea with Tartarised Antimony, to which is appended Instructions for the Guidance of the Public; the most simple and efficient to diminish its Mortality. By J. LANGFORD, M.R.C.S., late Resident Surgeon to the

Knott Mill Cholera Hospital, Manchester. 8vo. pp. 34. London, 1833. J. Ridgway.

We shall notice this essay at our earliest convenience.

Outlines of the Course of Lectures on Military Surgery, delivered in the University of Edinburgh. By Sir GEORGE BALLINGALL, M.D. F.R.S.E. Pp. 589. Adam Black, Edinburgh.

CORRESPONDENTS.

Baron Alibert.—We are greatly obliged by the communication, and are gratified that the celebrated author of the best work on Cutaneous Diseases approves our version of his work.

Dr. A. Thomson.—We have to acknowledge the receipt of M. Ricord's Second Paper, the Anatomical Notes, and the Note on the Treatment of Cholera.

Mr. Rees.—We shall insert the article in our next.

A Subscriber.—The Glasgow degree will not entitle the holder to an examination at the Royal College of Surgeons in London, unless he has attended a surgical hospital for twelve months.

A Westminster Student.—All the lectures at the Westminster School of Medicine are virtually recognised, and it is unfair and unjust to insinuate the contrary.

The communication on Pericarditis will be inserted at our earliest convenience, and we shall feel obliged for further communications from the same quarter.

A Student at the Westminster Hospital, a Pupil of Mr. Guthrie's, a Pupil of the Little Windmill-street School, A. Z., E. H. C., A. B., and J. F. N. will find Mr. Guthrie's Introductory Lecture in this day's Journal, and his own defence, which is better and more powerful than any we could offer, against his calumniators.

A Student at St. Bartholomew's has no right to interfere in the private arrangements of the lecturers. Students should attend to their own affairs, and leave those of others alone.

Medicus.—The wax preparations of human anatomy, and development of the embryo and gravid uterus, executed by Dr. Talrich, may be inspected at M. Alexandre's, Great Russell Street, and ought to be in the museum of all large schools.

Dr. MacAdam's lectures have been received, and we request to hear from our Dublin correspondent as early as possible. We wish he would forward Dr. Jacob's lectures, as we have already intimated.

Errata.—In Professor Cooper's 57th lecture, p. 290, column 2, line 18, for *ligatures*, read *ligatures of reserve*; line 32, for *cutaneous*, read *extraneous*.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

London Medical and Surgical Journal.

No. 90.

SATURDAY, OCTOBER 19, 1833.

Vol. IV.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LIX., DELIVERED FEB. 27, 1833.

GENTLEMEN,—In the last lecture I was considering the peculiar swelling of the median-basilic vein, occasioned by a communication being accidentally formed between that vessel and the brachial artery, a case that has received the name of *aneurismal varix* or *venous aneurism*. Here is a preparation exhibiting this kind of disease, the identical specimen, from which the engraving shown to you at our last meeting was taken. In this case, as I then told you, Sir C. Bell was obliged to tie both the branches of the brachial artery, which divided higher up the arm than common, and the limb mortified. An example, having a similar result, occurred some years ago at York. I think, that you should not operate for aneurismal varix on light grounds; that is to say, if the tumour be stationary and not the cause of much inconvenience, do not take up the brachial artery, for the event is uncertain. No doubt, the reason why Sir Charles Bell tied both the branches of the brachial artery was, because after one had been secured, there was still sufficient arterial blood entering the vein to produce an undiminished pulsation of the tumour. It seems to me, gentlemen, that it is not difficult to see the reason why, in these cases, mortification is so liable to occur after the operation; for a considerable part of the blood, which ought to pass onward for the nutriment of the fore-arm, enters the vein at the bend of the elbow, and is returned to the heart, without having served any useful purpose; and then, when a still further diminution of the supply of blood to the hand and fore-arm is produced by tying the artery, there must be a more considerable chance of the

operation producing mortification, than if the artery were tied for a common aneurism.

I have already apprised you, that in the early stages of a venous aneurism, pressure merits trial. You may conceive, indeed, that the pressure would, in some instances, obliterate the communication between the dilated vein and the aneurismal sac, when such a sac happens to be produced between the artery and vein; and that, under these circumstances, the impetus of the blood, which would no longer get into the vein, would make the aneurism under the vein increase in a serious degree. I have been informed, that a case, illustrative of these points, presented itself, the summer before last, at St. Bartholomew's Hospital, and that, after the communication of the vein with the artery had been obliterated by pressure, it was necessary to take up the artery for the subjacent false aneurism. However, it is right you should be aware, that pressure might obliterate the two openings, namely, that between the vein and the subjacent sac, and the other between the sac and the artery, and then a perfect cure would follow, as is illustrated in this preparation, in which you see the remains of a small sac between the artery and vein: this is filled with coagulated blood, and its communication with the artery and vein obliterated. You may also observe within the artery, which is slit open, a mark, denoting where the aperture, occasioned by the puncture of the lancet, was situated. This case was under the care of Mr. Oldknow, of Nottingham, who sent the parts and the history of them as a present to this University. I need not say, that it was not this gentleman who transfixed the vein and injured the artery, but a person of my name, though not, I believe, a regular practitioner. This case, then, proves that, even when there is a common aneurismal sac between the artery and vein, pressure may cure the disease. The pressure was maintained for some months before the pulsation in the tumour ceased.

Gentlemen, the plate, to which I wished to direct your attention in the last lecture, I will now show you: it relates to phlebitis, and illustrates some of the principal circumstances in that interesting disease. In the first place,

VOL. IV.

A A

you will see the veins, which are inflamed, thickened, and knotty, looking as if they were actually filled with anatomical injection. You may also observe, that their vasa vasorum are much enlarged. Then the basilic vein, which has been laid open, shows the effects of phlebitis in its different stages; the lower part of it being filled with pus, and the middle with coagulable lymph, in the centre of which is a quantity of pus; while the upper part is entirely blocked up with coagulable lymph, and a portion of the canal of the vessel obliterated. In this case, which was brought on by a gun-shot wound, a ball having passed through the middle of the biceps, the patient was attacked with phlebitis five weeks after the accident, and died on the fifth day from the commencement of the disease. This circumstance is illustrative of the fact, that phlebitis, when it proves fatal, does so very rapidly, the patient sometimes dying on the third day, and seldom living beyond the seventh or eighth. The same plate shows another circumstance, namely, the formation of collections of matter in parts at some distance from the seat of the phlebitis: thus, there was in this case a considerable abscess under the deltoid muscle, and another in the capsule of the shoulder-joint. Both these collections were quite distinct from each other—there was no communication whatever between them. In the substance of the biceps, there were also various small collections of matter, some of which seem to be really situated within small veins, while others appear as if effused from them into the cellular membranes. This case proves, likewise, what I mentioned to you the other evening, that phlebitis may extend both upwards and downwards; it has, however, a greater disposition to extend in the course of the circulation, but sometimes it spreads at the same time in the other direction; for here the cephalic, the basilic, the median, the cubital, and the radial veins are all affected. I consider this a very instructive plate, as it shows all the principal circumstances connected with phlebitis, as far as the veins themselves and the local appearances in the limb are concerned.

The next subject, gentlemen, which claims our consideration, is that disease of the veins in which they are swelled, thickened, and knotty; a condition in which they are said by surgeons to be *varicose*, or to constitute *varices*. A vein affected with this disease becomes thickened, knotty, and tortuous: it is, in fact, lengthened; but if we were to take into the account all the various enlargements of veins, and consider them as species of varix, we should then have several varieties of the disease. Some pathologists take this view of the subject, and among them is Professor Andral, who describes the several kinds of enlargements of veins which he has met with in dissection. It is questionable, however, whether some of them can rightly be classed with *varices*. I believe that, in this country, sur-

geons do not generally admit so many different forms of varicose veins as Andral does; for he describes under the term *varix*, the simple dilatation of the veins observed around every chronic tumour. This may be a mere dilatation of the veins, without any knotty or tortuous appearance of them. This blue-coloured fulness of the veins may always be noticed around chronic tumours, especially those of the breast. Such is Andral's first variety. In his second, the coats of the vein are not thickened, but rather thinner than natural, though the vessel itself is enlarged. In his third variety, the veins are tortuous, and, at the same time, dilated. In the fourth, their coats are thickened, with interspaces between the diseased portions: of course this would give the veins a knotty appearance, forming that kind of disease which we commonly regard as true varices. In the fifth variety, which Andral has traced by dissection, there are septa formed in the veins, dividing their cavity into cells which are filled with coagula. The last form of varix noticed by this pathologist is one which is not unusual at the extremity of the rectum, in piles of long standing; in it there are not merely septa, but perforations in the coats of the veins, by which communications are established between the interior of the vein and the surrounding cellular tissue, which is thickened and diseased. Thus, many hæmorrhoidal swellings at the extremity of the rectum are not simply varicose veins, but veins which have undergone the changes I have described; and it has sometimes been questioned whether some of these swellings are really veins at all, or even connected with veins, because they appear so hard and solid.

Some of the forms of varicose veins, now described to you, when superficial, must interfere with the functions of the valves, and in many instances these parts are diseased or imperfect; hence one cause of the origin and increase of the disease, especially in the lower extremities; for the column of blood, not being properly supported by the impaired valves, presses unduly on the coats of the veins, so as to bring on a thickening of them, and a swelling of the vessels themselves.

The large size of varicose veins in the lower extremities, and the great disfigurement they produce, cannot have failed to strike your attention in walking round the wards of any of the metropolitan hospitals. You will see in some of the working classes the veins of the leg enormously enlarged; yet such persons frequently bear the disease without seeming to feel any great inconvenience; and it is only when a considerable degree of pain has been produced in consequence of their having worked harder than usual, that they will submit to confinement.

Varicose veins of the lower extremities have the effect of bringing on some obstruction or derangement of the capillary circulation, a fact which I mentioned to you when speaking of varicose ulcers. Now this obstruction of the

capillary circulation is well known to create a disposition to chronic inflammation, which frequently advances to ulceration; hence you will find, that patients, who have long laboured under varicose veins of the leg, are generally afflicted with ill-conditioned ulcers on the same parts. The veins most subject to varix, are the great saphena vein and its branches, the spermatic veins, and the hæmorrhoidal veins. I may state, as a general fact, that those veins are most liable to varix, in which the blood has to ascend a considerable distance against its own gravity. Hence the veins of the lower extremities are those in which the disease is most frequent. There is an additional reason, why the veins about the rectum should be so frequently attacked with varix,—for those individuals, who lead sedentary lives, and are habitually constipated, have their bowels loaded with hard dry excrement, the pressure of which on the hæmorrhoidal veins must contribute very much to bring on *piles*, (for so the disease is called when its seat is in the hæmorrhoidal veins). Here also another circumstance is sometimes concerned in the production of varicose veins, namely, the pressure of the gravid uterus on the veins of the pelvis and rectum. In this way, a disposition to piles is produced, and also to varix of the veins of the leg. The tall stature of some persons may be regarded as conducive to the formation of varix, on account of the greater length of the veins, and consequently the more considerable extent of the column of returning blood.

With regard to the treatment of varicose veins, you must understand very well, without my reminding you of it, that one of the principal indications is to remove the exciting cause: thus, in pregnant women, no effectual amendment can be expected until after delivery; you may palliate the disease by keeping the patient in the recumbent position, but generally no effectual relief can be given, till the exciting cause has been removed. In all cases of varix, it is an important object to prevent constipation, and this more especially when the veins of the rectum are those affected. In every instance, however, I advise you to be particularly careful to obviate constipation; and, when the veins of the lower extremities are varicose, and no active degree of inflammation is present, pressure may be employed with advantage, by means of bandages or laced stockings. Rollers, made of India rubber, are now sold for this purpose, which answer exceeding well. But you will frequently be called to patients with varicose veins in a painful and inflamed state, the skin over the diseased veins being very red, or discoloured with a brown tinge, and the cellular substance around them much swelled. In such a case, you will be obliged to dispense with pressure at the commencement, as the patient cannot endure it. Here you must first enjoin perfect quietude, and the recumbent position, either on a sofa or in bed; you must

also make use of cold applications; the limb should be covered with cold evaporating lotions; and if, by these means, the patient should not be relieved, you may try fomentations, and a poultice made of bread and water, or bread and the lotio plumbi acetatis. Of course, you would not neglect aperients and other antiphlogistic means. Such treatment is to be persevered in, till the limb is quiet, when it will usually bear pressure with advantage. The inflammation of veins, arising from varix, does not frequently assume the dangerous form that we observe in phlebitis, from the mechanical injury of a large vein; it does not frequently extend far along the vessel towards the heart, so as to produce danger by the constitutional disturbance excited, though it has a great disposition to affect the surrounding parts, such as the skin and cellular membrane, which become inflamed, and more or less discoloured and thickened. However, by injudicious treatment, such as cutting out the diseased portion of the vein, or the application of a ligature to the vessel, extensive phlebitis has sometimes been brought on, and the patient destroyed by the febrile disturbance consequent to it. One inconvenience, attending varicose veins, is the strong tendency they evince to inflame and ulcerate, in consequence of which, the patient may have copious and even dangerous bleeding. With regard to the plan of curing varicose veins, by obliterating with a ligature the trunk belonging to the branches principally affected, I may say, that the unsatisfactory results, which the treatment, founded on this principle, has frequently had, have induced the best modern surgeons to avoid it, except in very urgent cases where the patient is suffering severely, and no other means of relief can be found. For instance, no one would now think of cutting out the diseased portion of the vein, unless the symptoms were excessively severe; for it is known, that making too free with a vein of important size is liable, as I have told you, to produce the dangerous affection called phlebitis. Neither would any one at the present day voluntarily and readily apply a ligature to the vena saphena major; the case must be an urgent one indeed, or have some peculiarity to justify such practice. Instead of this proceeding, another has been proposed, namely, that of passing a knife under the vein, and dividing it, without carrying the instrument completely through the skin. This method seems less subject to be followed by a dangerous degree of phlebitis, than Sir Everard Home's operation of exposing the vein and tying it; and, if the obliteration of the trunk of the vena saphena major be judged necessary, Mr. Brodie's method should be preferred. Mr. Mayo usually cures varicose veins with caustic.

The various enlargements of the spermatic and hæmorrhoidal veins, I will describe when I come to the subject of diseases of the testicle and rectum.

Gentlemen, the next class of diseases to which I propose to invite your attention is one of considerable interest, I allude to the *diseases of bones*. In my observations on the question,—how far lost animal substances can be produced? I told you, that there were two textures, which seem to have a greater power of reproduction than all the rest, namely, the skin and the bones. In all general circumstances, the bones resemble, in their organisation, the other parts of the system, being supplied with arteries, veins, absorbents, and nerves; and their chief peculiarity consists in their containing a proportion of phosphate of lime, to which they owe their rigidity, strength, and solidity, so essential to the various purposes of the skeleton. The changes, which the bones undergo in the commencement, progress, and decline of their diseases are all remarkable for a peculiar slowness of character; and, when you begin to make observations in practice, you will soon discover, that the different processes, which take place in the diseases of the soft parts, are in general considerably quicker, than those attending the morbid states, or the following accidental injuries of the bones. No doubt, this fact is partly owing to the circumstance I have mentioned, namely, the introduction into their texture of that lifeless inorganic matter—phosphate of lime, and also to their inferior degree of nervous energy. Under such circumstances, we should hardly expect, *à priori*, that they would have so wonderful a power of repairing their injuries as they actually possess: yet they have even a greater power of this description than perhaps any other texture, except the skin; but, for this purpose, they naturally require time, and sometimes a considerable length of time. These circumstances will be convincingly illustrated in the account I am about to give you of this interesting subject. The first affection, to which I shall invite your attention, is *inflammation of the bones*, and *periostitis*, or inflammation of the periosteum, or fibrous membrane with which they are covered.

Periostitis is a term, which was first introduced by Mr. Crampton of Dublin; indeed, he was the first person who noticed and described *idiopathic periostitis*, or periostitis that begins as an original affection; for the disease has two varieties, the *idiopathic* and *symptomatic*; the latter division comprehending that inflammation of the periosteum, which is the effect of disease in the constitution, such as scrofula, syphilis, or unfavourable states of the health, often accompanying the careless and injudicious use of mercury. Ever since the venereal disease has been attended to, surgeons have been aware, that inflammation of the periosteum sometimes followed it; they, therefore, acquired a knowledge of periostitis in its symptomatic form, but it remained for Mr. Crampton of Dublin to give a description of the idiopathic example of the disease; and, perhaps, it was owing to the great frequency,

with which periostitis came on after certain specific diseases of the constitution, that surgeons so long overlooked the idiopathic variety of the complaint. Indeed, idiopathic periostitis very frequently occupies precisely the usual seats of the syphilitic form of it, the swelling may be the same in point of situation; and hence another reason why the disease should have been overlooked.

Periostitis and inflammation of the bone frequently exist together; indeed, it has been doubted, whether the surface of the bone can be inflamed without the periosteum participating in the inflammation; but it appears, that the affection may commence in the periosteum, and if it go on for some time, the bone will become affected, or the bone may be inflamed in the first instance, and, after a time, the periosteum becomes affected secondarily; we may also have a more limited degree of inflammation in one texture than in the other.

Periostitis presents itself under the *acute* and *chronic* forms, and its symptoms differ accordingly. In the *chronic* the pain is less severe than in the acute. The *paronychia periostei*, or the deep-seated paronychia, or whitlow, which affects the phalanges of the fingers and their periosteum, affords us a familiar example of periostitis in its acute form. This disease is followed by an immense swelling of the finger, which seems ready to burst; the part is hardened and œdematous, or affected with erysipelatous inflammation; matter forms, and there is generally a sloughing of the integuments of the fingers and hand, with abscesses between the muscles of the forearm. This is a common example of acute periostitis, and is often described under the name of *paronychia maligna*.

Periostitis is most disposed to occur on those bones, which are situated near the surface of the body, and, on this account, the disease may easily be confounded with nodes; for, when I come to the venereal disease, I shall explain to you, that when it attacks the bones, it has a disposition to invade the most superficial ones in preference to others, which, however, do not always escape. Periostitis, also, sometimes attacks the fibrous membrane of deep-seated bones, for example, the femur; and then the disease is almost always found to be situated in the lower third of the thigh, sometimes extending as far as the joint, and producing a swelling of it. Professor Graves of Dublin has delivered several interesting clinical lectures on periostitis, and I observe, that he divides the disease into two kinds, the *circumscribed* and the *diffused*; the latter he represents as following accidental injuries or cold; the circumscribed he says, is generally the result of specific diseases of the whole constitution, for example, scrofula, syphilis, and that impaired state of the system brought on by an injudiciously conducted mercurial course.

The *local symptoms* of periostitis vary as well as the *constitutional ones*. When the

disease is chronic, it is subject to exacerbations at night, which is another circumstance liable to make the practitioner suppose the disease to be a node; the increase of the pain at night produces a prejudicial effect on the general health. Inflammation of the periosteum, gentlemen, is more rapid in its development than inflammation of bones, this is a circumstance in which the affection differs from a true node; there is also more pain and fever, and the inflammation is quicker in its course. In an early examination of the part, you will generally find, that the swelling has a degree of elasticity about it, and that it is not so firm as real nodes, in consequence of an effusion of a quantity of a coagulating lymph, under the periosteum; you will also notice, that the inflammation is more acute than that of a true node, and more disposed to spread to the neighbouring parts. In severe cases, there will always be a great deal of fever; the functions of the digestive organs will be seriously disturbed, and you will mostly find that the patient has a sallow unhealthy look. I believe, when the disease has not been the effect of accidental external violence, an impaired state of the constitution and a sallowness of the complexion generally attend it. In some instances, the inflammation goes on to suppuration, and the pus, which forms, is commonly seated between the bone and the periosteum. The inflamed periosteum is sometimes thickened without an effusion of fluid under it, and then there may be increased vascularity of the bone, and increased adherence of the periosteum to its surface, attended with severe suffering and violent disturbance of the health. This form of the disease, if not relieved in a moderate time, terminates in the conversion of the periosteum itself into a fibro-cartilaginous substance. It is followed by a considerable swelling of the bone itself, so that the disease assumes very much the appearance of a node; the surface of the bone itself becoming altered, and bony matter being deposited under the fibro-cartilaginous substance, while the wall of the original bone is removed, and a communication established between a kind of cancellated texture in the new bone and that of the old one. In this manner the new formation seems to constitute part of the original bone. There is no preparation, illustrative of these facts, in our museum, but Professor Graves refers to some in the collections at Dublin.

There are certain predisposing and exciting causes, which taken together are found to have a great influence in the production of periostitis. Thus derangement of the health, and great mental anxiety will predispose to the complaint; and, if a person in such a state receive a blow on the shin, he may have a considerable degree of periostitis, much more severe than if the same accident had happened to a healthy subject. Then it is known, that, in particular states of the constitution, periostitis is frequently produced by an injudicious and incautious use of mercury, either by its employ-

ment in immoderate quantities, or by its being given when the patient does not take sufficient care of himself, and exposes his person continually to a damp, cold atmosphere. Rheumatism is known to be one of the causes of periostitis. It is also remarked that a large proportion of those who suffer from periostitis, are persons of the middle age; hence it has been inferred that this period of life predisposes to the affection; but the fact is, it is not unfrequently met with both in old and in young persons; in the latter as a symptom of syphilis, or as a consequence of that affection and the abuse of mercury, or else as a symptom of scrofula.

Gentlemen, the *treatment of periostitis* differs according to circumstances. When it exists in the *acute form*, it is necessary to employ such local and constitutional means as are calculated to subdue inflammation generally; and if these fail, you must have recourse at once to an incision through the inflamed membrane. I am now speaking more particularly of the *idiopathic form*. Let me say then, that if it be an original disorder, independent of any specific disease of the constitution, you should commence with anti-phlogistic measures, and, if these fail, you must have recourse to other plans; one of which consists in making an incision through the periosteum down to the bone. It is found, that idiopathic acute periostitis causes intense agony, a circumstance which pathologists generally account for by the consideration, that the periosteum is a fibrous membrane, inelastic, and indisposed to yield in proportion to the accumulation of matter underneath it. This view necessarily sanctions the rule to make an early and free incision through the membrane in every case of idiopathic periostitis, which does not readily give way to anti-phlogistic treatment. When the inflammation arises, (as there is no doubt that it often does,) from the further impairment of a disordered constitution by an injudicious and careless course of mercury, that mineral should be discontinued; for were you to persist in its employment, you would be keeping up the exciting cause. No doubt mercury alone will not produce periostitis, unless the constitution be at the same time in an impaired state, or the person expose himself to cold while taking it; for patients with diseased liver in warm climates, take great quantities of mercury without suffering either from periostitis, or nodes. The disease therefore, seems to be the combined effect of the three causes; the first the effect of the venereal disease on the system; the second the effect of the mercury given carelessly and injudiciously; the third an impaired state of the health existing at the same time. Whether a scrofulous constitution predisposes patients, who are using mercury, to periostitis, may be a question. But, undoubtedly, inattention to diet and regimen, and a tendency to rheumatism, will facilitate the occurrence of the disease during a course of mercury.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE VIII.

Causes of Monstrosities—Hygiene, or Rules for the Management of Women during Pregnancy, Parturition, after Delivery, and during Lactation, or Suckling.

GENTLEMEN,—There is a great diversity of opinion among authors as to the causes of monstrosities, or deformed infants. The ancients ascribed them to whims of the imagination, to the action of the stars, and to the influence of the mind after the sight of hideous objects. Winslow, Prochaska, Gall, Spurzheim, and many others, attributed them to primitive defects in the germs; while Lecat, Sandifort, and most of the moderns, believe them to be purely accidental. Chaussier, Meckel, Tiedemann, Geoffroy Saint-Hilaire, and those who have recently written on the development of the fœtus, ascribe them to an arrest of growth. The last-named renowned physiologist has made the greatest researches and numerous observations on monstrosities, and has arrived at the conclusion, that abnormal adherences between the embryo and ovum, or its appendages, are the real causes of them. It is also very evident, that pressure made on the abdomen by tight lacing to disguise pregnancy, or to preserve the figure, and various diseases of the placenta, which may retard or impede the circulation of the blood between the mother and infant, may prevent the proper growth of the latter and produce deformities.

There can be no doubt that the mode of life of the mother, the state of her mind, health, diet, and exercise, will indirectly affect the embryo in the first days of its existence. Some women experience a train of new sensations from the instant of conception, though this very rarely happens,—not perhaps in one instance in ten thousand. Pregnant women, in general, are more excitable and sensible, and suffer from innumerable nervous and anomalous symptoms. Some are exhilarated, others depressed; some become excessively nervous, bilious, or hysterical; others enjoy much better health than at any former period of life. Some, who are naturally gay and amiable, become sad, melancholic, and unsocial; while others enjoy the highest spirits. The appetite and taste are altered by pregnancy. The vulgar attach great importance to the different tastes and longings; these, as a general rule, may be gratified whenever wholesome aliments are desired, but not otherwise. It would be wrong for a pregnant woman to eat crude vegetables, turnips, carrots, and similar foods without culinary preparation.

A voracious appetite will require a greater quantity of aliments than ordinary, but not so much as would be injurious; a variable appetite will be satisfied by frequent slight repasts; and a diminished appetite will be stimulated by such foods as the woman desires. It is not necessary for the growth of the fœtus that the mother should take more food than usual; she may take it to satiety. Every description of high seasoned foods, and the excessive use of wines, spirituous or fermented liquors, brandy, whiskey, gin, rum, ale, porter, stout, &c., tea, coffee, chocolate, are highly injurious both to the mother and infant. These liquors injure the pregnant woman, and expose her to danger during parturition, and to fever or inflammation afterwards, while they arrest the growth and destroy the health of the infant. It is impossible to lay down rules for the quantity of diet or drink, but nature is the best guide. The mind should be kept tranquil, there should be no fear entertained about delivery, because women, as well as all animals in general, do well; our domestic animals invariably do well, and so do women, when they attend to the rules laid down for their general health. Parturition is a natural process in a state of health; and bad labours are comparatively few in number, as appears by the reports of all the lying-in hospitals in the civilised world. Depression of mind as to delivery may cause convulsions or mania during pregnancy, labour, or after delivery.

The dress of a pregnant woman should be suited to the season, and always loose. Tight lacing is highly injurious, as it impedes the breathing, prevents the development of the abdomen and breasts, arrests the growth of the infant, and inevitably ensures inflamed breast and sore nipples after delivery, thereby subjecting the mother to great suffering, and depriving the infant of the aliment which nature intended for it. There is no objection to the proper use of stays or corsets during the first five or six months of utero-gestation, but after that period they should be worn loosely. The simplest aliments, of the easiest digestion, and containing most nutriment in a small volume, are those most appropriate for pregnant women. They should take slight repasts, and never overload the stomach. The vulgar prejudice of forcing them to take more food than in a state of health is highly pernicious, and induces indigestion, flatulence, spasm, diarrhoea, vomiting, &c. The appetite is capricious, and hence the woman often fancies foods she disliked before conception, and dislikes those she always preferred. The sight of animal food disgusts some women. The diet should consist in wholesome aliments, such as beef, mutton, lamb, fowl, &c., roasted or boiled in preference to broiled, baked, &c., and all salted or smoked aliments ought to be taken sparingly, if at all, as they generally derange the stomach. The flesh of young animals, as veal, lamb, kid, chicken, and certain kinds of fish, are less nutritious than the

former, but do not excite the stomach so much, and are therefore considered lighter. Fatty aliments, as pork, duck, eel, butter, oil, &c., are easily digested; but generally disagree with nervous, bilious, dyspeptic persons, and especially during pregnancy, when there is generally more or less nausea. Farinaceous foods, as bread, rice, potato, peas, beans, sago, arrow-root, tapioca, and salep, are highly nutritious, though they may induce heartburn, flatulence, and indigestion. Mucilaginous aliments, as carrots, turnips, parsneps, cabbages, asparagus, ought to be used sparingly by pregnant women and those who suckle their infants; and the black or red pepper should be used with them. Sweet foods, as sugar, figs, dates, fruits, &c., should be used in moderation. A moderate use of wines, ales, porter, &c. is advisable. As the stomach is irritable and delicate in most pregnant women, it is highly necessary that the food should be well masticated or divided with the teeth, to render it more fitted to be acted upon by the stomach; and drink should be used sparingly, for if the gastric fluid be too much diluted, it cannot act on the food in an efficient manner. These precepts apply to all persons, but more particularly to pregnant and suckling women.

Tight lacing in the advanced stage of pregnancy will induce many painful and dangerous diseases, obstinate coughs, spitting of blood, palpitation of the heart, swelling of the lower limbs, enlargement of their veins, piles, costiveness, heat, and scalding in evacuating the bladder, &c.

The pregnant woman should sleep in a capacious and airy apartment, and take repose for eight hours. She ought to retire to bed at an early hour. Moderate exercise is proper during the whole period of utero-gestation, but should never be taken to fatigue. Walking is the best kind of exercise. Women living in the country, or in the lower ranks of life, bear great exertion and labour, and have the easiest deliveries; but they are accustomed to exercise from their infancy. The motion of carriages, chariots, or vehicles badly hung, long journeys, walks, running, dancing, raising or carrying heavy weights, falls, slips, and blows are the commonest causes of hernia, uterine hæmorrhage or flooding, miscarriage or premature labour. Moderate carriage exercise or sailing may be used with safety. According as the period of parturition approaches, women have more occasion for rest and repose, and should therefore take less exercise, especially those who are liable to, or threatened with, abortion; and sometimes they should be confined to their apartment, placed on a couch, or confined to bed for days or weeks.

Abortion or miscarriage is much more injurious to health than parturition, as the loss of blood and the debility induced are greater. When it happens once it is difficult to prevent its recurrence on future occasions; and therefore medical practitioners judiciously consider

it a most dangerous disease. Balls, theatres, crowded assemblies, all public sights, exhibitions, and seeming dangers, should be avoided by pregnant women; as in all crowded meetings the air is heated and impure. Long watchings, or want of rest, as well as powerful emotions, excite the nervous system, impair the strength, and derange the whole functions of the body. Violent passions are always injurious during pregnancy. I have already stated, that frights, longings, and despondency may retard the growth of certain parts of the infant during the early period of its existence; but this cannot happen after the second month when it is fully formed. Lastly, pregnant women should indulge in nuptial commerce with reserve and with caution, as it may disturb the womb and bring on abortion, as very frequently happens. The lower animals avoid copulation after the female is with young. The womb is easily disturbed in the first and last months of pregnancy. It is imperfectly closed soon after conception, and is very much distended in the last months, so that the slightest causes may excite to expel its contents, or induce abortion or premature labour.

Of all the precepts for the preservation of health, that of regulating the bowels or procuring an evacuation daily, is perhaps the most important. No person, male or female, can be in perfect health who has not an alvine evacuation daily. This statement would appear incorrect to non-professional persons; but no physiologist can dispute it. Those whose bowels do not act daily suffer from some degree of indigestion or hysteria, or a thousand other incipient diseases. Regulation of the bowels during pregnancy preserves the health, prevents a vast number of disorders incidental to this condition, ensures a natural and safe delivery, a "good getting-up," and an immunity from the fevers and inflammations consequent to parturition and the puerperal state, and a healthful vigorous infant. The medicines usually employed as aperients, during utero-gestation or pregnancy, are castor oil, lenitive electuary, Epsom salts, or mild clysters; but the following pills are much better. *R. Ext. colocynth. c. ʒij; ext. hyoscyami, ʒj; hydrarg. subm. gr. xij—xv; olei menth. pip. mʒ; in pilulas xv. divide, ex quibus sumat ægra unam vel duas hora somni, pro re nata.* One or two of these pills taken at bedtime, occasionally, or as often as may be necessary, will act mildly and efficiently. They should be used during the last three months of pregnancy, two or three times a week, because the pressure of the enlarged womb, at this period, on the bowels, generally causes obstinate costiveness, piles, swelling of the lower limbs, derangement of the stomach and intestines, heart-burn, water-brash, spasm, &c., &c., all of which will be prevented by proper attention to the bowels.

As a general rule, pregnant women should avoid all causes of irritation, mental, corporeal, and mechanical as these will increase

the determination of blood to the womb, or provoke abortion or premature labour. If robust and vigorous women pursue their ordinary avocations with safety, it does not follow that nervous or delicate persons can do so. Even the first should moderate their avocations or exertions, their aliments, exercise, and pleasures; but the greatest management is necessary for the latter to preserve their offspring until the time of parturition, and to keep them in good health.

Pregnant women ought to avoid air that is too hot or too cold, or such as is charged with odoriferous exhalations. All substances that confine or derange the bowels, as certain aliments, or medicines, opium, laudanum, chalk, &c., all severe study, night watching, or too long indulgence in bed. They ought not to be alarmed about frights, marks, or future consequences, or at those false and frightful tales told about parturition, which are scarcely ever true, and generally exaggerated by the narrators to prove their knowledge and experience. Young, healthful, well-formed women, who are pregnant for the first time, should entertain no fears, as it rarely ever happens at present, that a woman dies in labour, and never afterwards, without imprudence on her own part, or ignorance or mismanagement on the part of her male or female attendant. Besides, there is no case of labour which can possibly happen but may be managed, and the woman's life preserved. It is really lamentable to listen to the fears and apprehensions of young pregnant women, which are generally excited in their minds by ignorant midwives and domestics, and, indeed I may add, mothers and acquaintances. But we cannot be surprised at this, as there is no work in our language for the instruction of the other sex, as regards parturition, pregnancy, confinement after delivery, or the management of new born infants. All their information is derived from medical practitioners and nurses; and the majority of both classes of advisers has been hitherto extremely incompetent. That there are as able and as scientific practitioners in this as in any other country cannot be questioned for a moment; but the study of obstetric medicine was only enforced five years since in this section of the United Kingdom, and therefore was previously neglected by a preponderating proportion of the profession. Even now, the injuries that are daily inflicted upon parturient women and their helpless offspring by incompetent practitioners and ignorant midwives are truly frightful. It is an indelible disgrace to the medical corporations in this kingdom to have excluded the study of midwifery, and to allow ignorant persons, both male and female, to practise so difficult and dangerous a department of medicine.

The pregnant woman should, therefore, procure the best medical aid for the period of delivery that circumstances will permit; and she should never employ a midwife, if she can

procure a medical practitioner. The presence of a medical practitioner, and his confident assurance of her safety, will inspire hope, and expedite delivery; and should any untoward event occur, a midwife who has not received medical instruction, and few in this kingdom have, is of no use whatever. Let the parturient woman place the fullest confidence in the advice of her medical attendant, strictly follow his directions, have no opinion of her own, and pay no attention to any contrary advice that may be proposed by her nurse. During labour, she must always remember that time and patience are necessary for her delivery. If her medical attendant assures her that she is safe, she must have patience, and avoid gusts of passion, which often induce fatal convulsions, or even mania. Fortunately for humanity the medical practitioner can now abridge labour, and save an immensity of suffering, without any operation, but merely by the exhibition of medicine. I am as convinced of the power of the *secale cornutum*, as I am of opium. An uneducated midwife can afford no relief whatever, and generally does harm by her interference. I never knew a woman who was attended by a medical practitioner, who on any future parturition would admit a midwife. I have often heard women remark how differently they were treated by their female and their medical attendants; and that females are much more unfeeling than those of our own sex. Midwives have great influence over the lives of mothers and their infants, and they either preserve the human species by their knowledge, or destroy it by their ignorance. This position was admitted in France, nearly a century ago, and led the government to order all midwives to receive medical instruction; and not to practise without it under heavy penalties. They should be decent, modest, moral, religious, sober, regular, and humane in their conduct, and on no account commence practice without having received medical instruction. They should attend as speedily as possible in all cases, regulate the apartment, bedding, dress, intended for the woman and infant, and prepare the food for the parturient woman. They should never attempt to dilate the genital fissure, "to make room for the infant," they should sit and observe nature. They ought to refrain from telling frightful tales, and likewise from administering strong liquors, which are not necessary in one case in a thousand, unless where the patient is delicate or has suffered a long time; animals do well in labour without ardent liquors. When the infant is passing into the world, its head should be supported while its body is being expelled, and so soon as it breathes the navel string should be firmly tied with some strong tape or waxed thread, within an inch and a half of the abdomen, a double knot placed, and the navel cord cut with a pair of scissors. The infant ought to be enveloped in a piece of flannel, called a receiver, and a warm napkin applied to the mother. The patient may now have a little

brandy, or other spirit, or wine and water, additional bed covering put on, the wet clothes drawn from under her, and be left quiet. In general the placenta, or after-birth, comes off in half an hour or an hour after the birth of the infant. The woman should not be disturbed for an hour after delivery, or, in other words, the bed adjusted; or, as the phrase is among midwives, "put to bed." During this hour the infant should be washed and dressed in the manner to be described hereafter, in an adjoining apartment. The mother should on no account sit up while her bed is being arranged, but be raised in the sheet between persons, or shifted on a couch, or on chairs covered with bedclothes. If she sits up, she may be seized with flooding, fainting, or falling down of the womb,—the prolapsus uteri of writers. When the placenta, or after-birth, comes away, or is expelled, a warm napkin should be applied to the patient, and a bandage placed around the abdomen. Her head and shoulders should be raised, so as to facilitate the escape of the lochial discharge. The external genitals should be washed daily with warm milk and water.

On the fourth or fifth day the bed may be arranged, and the patient should be placed on her side, as before stated.

The diet of a puerperal or lying-in woman should be mild and unirritating, as gruel, arrow-root, sago, tapioca, prepared barley, barley-water, weak tea, coffee, &c.; and all sorts of animal food, as well as every description of spirituous or fermented liquors, plain or spiced, are highly improper, and may produce dangerous fevers or inflammations. Ardent liquors must be administered in very small quantities, even by the faculty, and are seldom necessary.

No broths, meats, eggs, or fish, are to be allowed until the fourth or fifth day after delivery, unless in cases attended with debility, as when the patient labours under consumption, liver complaint, or any other chronic disease. The lower classes, especially in the country, do well, as also the inferior animals, without high seasoned foods, spirituous, or stimulating liquids.

On the fifth day after delivery a little beef-tea, chicken-broth, calves'-feet jelly, fresh eggs, &c. may be given in small and repeated quantities; but should headach, flushed face, or rapid pulse be caused by any one of these it must be immediately discontinued. Delicate women may take animal food immediately after delivery, but this is an exception to the general rule, and very rarely to be adopted. When the mother has breast milk, it is unnecessary to give the infant castor oil, melasses, syrup of violets, or butter and sugar, as the bowels will be purged by the first milk, or often without it; but should they not be opened in twenty-four hours, half a teaspoonful of castor oil may be exhibited, and repeated in six hours if necessary. If the infant does not pass urine, some hours after its birth, the lower part of its

abdomen should be fomented with warm water, or decoction of poppies, and the genitals examined, lest there be any unnatural formation. It often happens, that the breast milk is not supplied at the time of delivery, and, in such cases, the best substitute for the natural food is five parts of cream, or sweet milk, with one of boiling water. The cream, or milk, should not be boiled, but warmed when required, by placing the vessel that contains it in warm water. The frequency of giving food will be described hereafter.

The woman may sit up on the fifth or sixth day after delivery if she feels able, and is of a strong constitution; but if delicate not for a longer period. She will feel giddiness on sitting up for the first time, pains in the back, loins, and lower extremities, which may continue for several days, but will gradually disappear. She should not attempt to walk about her apartment sooner than the ninth day, or so long as the discharge continues. This may be very much increased by sitting up, or attempting to walk; and the woman should not go into the open air or take exercise until it has ceased, which may not be for a month. She should remain in bed or on a sofa. It is difficult to lay down rigid rules on this head, as constitutions differ so much. One woman will be pursuing her usual avocations on the sixth or eighth day, and another not at the end of a month. There is great liability to fevers and inflammations of the most fatal description, and therefore the preceding precepts inculcated ought to be strictly attended to. The bowels may be opened with a tablespoonful of castor oil on the second or third day after delivery, provided there is a supply of breast milk; but if the milk has not formed the aperient will impede it, by causing a determination of blood from the breasts to the abdomen. If we wish to prevent the secretion of milk, in cases where the infant is born dead, we do so by opening the bowels freely. All strong liquors, exposure to cold, or too much heat, or sitting too soon, ought to be carefully avoided, as they may induce fevers or inflammations at any time during the first nine days, and sometimes as late as the second week. The chamber should be properly ventilated, and the temperature regulated according to the season, and the bed clothes should be sufficient to cause comfortable warmth, but not too warm, as then both miliary fever and a superabundant lochial discharge would be induced. When the breasts become hot and painful they should be fomented with a warm decoction of poppies and chamomile, and then drawn by a proper glass, or by the infant, or by an older child, or an adult. This subject I shall notice more fully in a short time. The woman should not rise from bed until the lochial, or child-bed discharge has ceased, for while it continues the womb is not reduced to its proper size in the unimpregnated state, and therefore all bodily exertion will disturb it, and render the discharge excessive.

Most women are extremely sensitive after delivery, and hence they should be kept perfectly quiet, all noise, and strong mental emotions, or improper aliments, either solids or fluids, being highly injurious; so great is the nervousness after delivery, that any cause of alarm may induce convulsions or mania, and any kind of improper food or drink, or exposure to cold, excite fevers or inflammation. It is an axiom with medical practitioners, that more women die after delivery than during pregnancy and parturition.

It generally happens that the breasts become hot and painful in a day or two after delivery, in consequence of the determination of blood from the womb to these organs, for the purpose of causing the secretion of milk. Warm fomentations, as already mentioned, and afterwards the application of almond or olive oil are usually employed, and then suction. There may be a slight fever for twenty-four hours, which is by no means dangerous, and is designated milk fever.

The secretion of milk, or lactation, is a part of the process of reproduction, and is essential to the well-being of the parent and offspring. It preserves the mother from febrile and inflammatory diseases, and it affords the aliment intended by nature for her infant. Every woman, whose constitution and health are good, ought to suckle her infant, but every one who is delicate, affected with chronic disease, or has little breast milk, should avoid it. When the nipple is too short for the infant to seize it, artificial suction will be necessary, and this is effected by means of breast bottles, or various other contrivances. The nurse, or some adult, must effect it in some cases, and in former times a young dog was applied for the purpose. Unless the tumefied breasts are relieved they are extremely liable to become inflamed. Artificial nipples, prepared teats, shields of wood, gum elastic, glass, and metal were tried, but of this the wood, covered with a prepared teat, is the best. Even this is liable to injure the infant's mouth, and should be laid aside as soon as the nipple is sufficiently elongated to be grasped by the infant.

During lactation the nurse should use nutritious aliments, such as described when speaking of pregnancy; she should avoid ardent liquors and acids, the depressing or violent passions, which deteriorate the milk, and she should not expose herself to the development of a new pregnancy. The infant ought to be applied to the breast every two hours, and even oftener when it is feeble, but after some days at the interval of three hours. It should be successively applied to each breast on every occasion, unless it is satiated with either, but some advise that one breast should be reserved for the next application. Regurgitations, or vomiting, with hiccoughs, are easily relieved by dill, fennel, or aniseed water sweetened. It should be always remembered, that the breast milk will be affected by the food and medicine taken by the woman who

supplies, and that it may be better in one breast than in the other. It may be superabundant in some, sparing or entirely absent in others. In the last case mercenary or artificial lactation will be necessary, and these I shall consider when describing the diet proper for infants. On the present occasion I notice those general rules, relative to pregnancy, parturition, puerperality, and lactation, which are most conducive to the preservation and development of the infant, before and after birth; and, in adopting this course, I follow the examples of many distinguished writers on the physical education of infants. It must be manifest to every one conversant with medical science, that unless the health of a woman, from the time of conception to the period of ablatation, or weaning, be good, the growth of her offspring will be affected. Every obstetrician, engaged in practice, will acknowledge, that some infants are born so feeble and delicate, that many of them expire immediately after birth, others in a few hours or days, several are reared with the greatest difficulty, and these are generally destroyed by the numerous diseases incidental to childhood.

It therefore follows, that the consideration of the rules for the preservation of the health of pregnant women, parturient, puerperal, and nurses, is essential to the conservation and vigour of infants, and to the increase of population. This conclusion appears to me to be incontrovertible, and I have acted upon it in the preceding lectures. I might have been much more minute in my description of the subjects, but having already described the hygienic and medical treatment of pregnant, parturient, and puerperal women in the former part of this course of lectures on midwifery, I considered a recapitulation unnecessary.

It now remains for me to direct your attention to the management of new born infants, or, to speak more correctly, the physical education of infants.

HOPITAL DES VENERIENS.

BLENNORRHAGIA IN THE HUMAN FEMALE.

BY PHILIPPE RICORD, D.M.P., &c., &c.

Translated from the new "Journal des Connaissances Medico-Chirurgicales,"

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

If the name of a disease ought to be a succinct definition of the same, so at least should it express one of its principal phenomena. The word *blennorrhagia* is quite as incorrect as *gonorrhœa*, *arsure*, *urethritis*, *urethro-vaginitis*, *chaude-pisse*, &c.; but if it conventionally serve to designate a certain lesion, and the collection of symptoms belonging to it, without any intrinsic value,—as the surname, for instance, indicates a man without describing him,—the name *blennorrhagia* is as good

as any other, provided it be adopted, and it be known what is spoken of when it is used.

Blennorrhagia, the occurrence of which is so common, has been studied by all the authors who have occupied themselves with venereal diseases, but has not always been explained in the same manner. Thus: some have regarded it as a form of the pox, while others have considered it altogether as a separate and distinct disease. Between these two extremes, of which the Society of Physicians of Besançon wished to judge in 1810, arises an opinion more rational, and which, not making of blennorrhagia an individual disease, recognises different species of it. This mode of regarding the subject, observation has forced me to adopt. Indeed, if we study the causes of blennorrhagia, the state of tissues which are the seat of it, and the symptoms accompanying or following it, we perceive that it is not always identical. However, to study it with advantage, and to comprehend it better, we must begin our researches at its source, and take its commencing point in the organs of the woman. In her, all its forms are, as it were, unveiled, by the facility with which every thing may be seen, and, what is wonderful in a host of facts, finds then a prompt and easy explanation. I am astonished that all the authors who have endeavoured to systematise have not regarded the question in the same point of view, and that, instead of building up theories respecting the meatus urinarius of the man, without being able to penetrate into his narrow canal, they have not thought of the facility with which they might have explored the vagina, and verified, by direct observation, what they only suspected in the man.

We have commenced, then, our study of blennorrhagia in the female, and by it we subsequently better comprehended and better explained that affection in man. In the woman we have seen, in reference to the causes, blennorrhagia quite spontaneous, and arising, independently of coition, under the influence of different pathological and non-venereal conditions, such as scrofula, scaly skin, eruptions (dartres), the second teething, &c. The seasons (spring and autumn) appear to me not foreign to its more or less ready development, and to its greater or less frequency. Sometimes it has been owing to a cause either mechanical or chemical, such as repeated masturbation, the abuse of premature coition, or of coition at a period when there is disproportion between the organs; the introduction into the sexual parts of foreign irritant bodies, solid or liquid; contusions and lacerations; certain exercises productive of much fatigue, &c. Sometimes its cause has been an impure connexion, well proved, or a contagious discharge has produced it; and, contagious in its turn, was susceptible of transmission; but then, it has always infected, at the first contact, the parts submitted to the contagion. Never, for instance, has the matter of a contagious blennorrhagia, applied to the organs

of generation, had, as its primary phenomena, a blennorrhagic ophthalmia, or produced an otorrhoea. When these accidents have occurred, and when they have been attributable to blennorrhagia without any proof of direct infection, the individuals affected by them still or previously had urethro-genital or anal blennorrhagia; never has matter, taken by the mouth, produced a discharge from the genital parts, as has been recently announced.

When I have sought, in the woman, what relations might exist between the particular causes and the precise seat of blennorrhagia, I have found none; indeed, we have been able to convince ourselves that whatever may have been the cause of the discharge, the vulva, the urethra, the vagina, and the uterus, have been liable to be affected singly or together. Yet it may truly be said (and we have advanced this in a Memoir read to the Academy of Medicine, and inserted in the collection of its labours), that the urethra in the woman is more frequently attacked singly, or at the same time with the rest of the genital organs, when the blennorrhagia is the result of an impure connexion.

In reference to the lesions of the tissues, we have found, as already stated, the urethro-genital mucous membrane, throughout its whole extent, or in isolated spots, of a more or less intense red, accompanied with tumefaction; heat, and redness, without there being, however, irritation, and presenting a condition, as it were, erysipelatous, susceptible of lasting a certain time, to disappear subsequently, or constituting but the first stage of a catarrhal inflammation, speedily giving rise to a variable morbid secretion, of which the differences hitherto appear to have no relation whatever with the particular cause of the affection. I have found, on examining the vulva, the vagina, and the neck of the uterus, the mucous membrane covered with papulae, or with more or less developed follicles, constituting a vaginitis, or papular utero-vaginitis—a *poorly* (*poorly*, Ricord), as I have named it, and capable of presenting it in different degrees; sometimes under the form of small spots of the size of a pin's head, more or less isolated, and more or less confluent; sometimes under the more advanced form of granulations, in some measure deprived of epithelium, and resembling fleshy granulations; and sometimes passed into the condition of true vegetations.

The vulvar mucous membrane, the urethral mucous membrane, as far as can be seen, and the vaginal and uterine mucous membrane, have frequently presented more or less numerous and extensive patches, resembling the surface of a blister in a state of perfect suppuration. In one woman, in the deep parts, and upon the neck of the uterus, the mucous membrane presented a most characteristic eruption of herpes phlyctenoides. Divers ulcerations have occurred in the different points of their extent.

Variable secretions have been found in the

urethra, the vulva, the vagina, and the uterus, but their difference has not appeared to be connected with one lesion of tissue, or with one cause more than with another. The acute state, whatever may have been the particular lesion, has given rise to the commencement of a secretion almost serous, or else normally mucous, but more abundant; becoming opaque, and then passing into the perfect purulent state, of a more or less deep yellow and green and sometimes tinged with blood. The chronic state frequently gives rise to a more or less thick milky secretion, and approximating to a caseous, or only to a more mucous consistence. The chronic discharge may also be purulent, brownish-red, or tinged with blood. The acute and chronic discharges may be completely inodorous, or on the contrary, have an excessively marked odour. When there are mucous papulæ, the odour, *sui generis*, is so marked, as to be characteristic in a great number of cases. In other circumstances it approaches more or less to the fœtid smell of cancer, or of feculent matter. However, the only differences resulting from the peculiar seat are, that the uterine secretions are always more mucous, thready, agglomerated into flakes (flocus), while those coming from the urethra, the vulva, and the vagina, constitute a liquid with molecules, more free and independent of one another.

The symptoms of blennorrhagia in the woman do not present differences always relative to the cause that has produced it: they are more connected with its precise seat and with its degree of intensity. Yet I have frequently seen at the Hôpital des Vénériens, women affected with discharges both acute and chronic, complain of no kind of pain, and be only in some measure advertised of their disease by the unusual spots upon their linen. Often, however, an inconvenient heat at the vulva, accompanied or not with itching, will announce the onset of the disease. When the urethra has been affected, the passage of the urine has been painful; there then existed a sensation of burning, pricking, or of cutting, as though a sharp instrument had traversed the urethra. There was then, according to the figurative and vulgar expression, *chaude-pièce, clap*. But this pain on making water has most frequently been wanting when there existed recent, acute, and very abundant urethral discharges, so that the absence of this symptom is to me a matter of no importance in seeking to determine the diagnosis. In vaginal blennorrhagia, accompanied or not with urethral discharge, the vagina has most frequently remained free from pain, when not irritated by foreign bodies. In some women in the acute stage, we have been able to introduce the speculum without pain; but in some patients coition or the slightest touch was insupportable. Defecation even determined pain, which was already more vivid from the moment that the feculent matters remained collected in the rectum.

In the uterine discharges, symptoms of metritis (inflammation of the womb) have frequently existed: thus, troublesome sense of weight in the fundament, heat of the neck to the touch, sensibility of the womb on direct pressure through the vagina, pain upon hypogastric pressure, sense of tension in the iliac fossæ, errors in the period of the menstrual discharge; sometimes, also, none of these symptoms existed, although the uterine discharge was acute and abundant. In the different states, general and syphilitic symptoms were sometimes manifested by disturbance of the circulation, of innervation, digestion, and of the urinary secretions. But most frequently blennorrhagia in the woman, whatever may be its precise seat and its intensity, is a purely local affection. The matter of the discharge of which I have already spoken, and the presence of which constitutes one of the most important symptoms, does not always occur in the same manner. To appreciate this symptom, we must know how to look for and to recognise it. If the chemises of certain women be examined, the anterior part, which is that soiled by men affected with the same disease, presents frequently no spot, unless the patients, through cleanliness, or some other cause, make use of it to wipe themselves; they must be looked for behind. Moreover, that is the part which they always show you, to make you judge of its qualities, or of its abundance. Do we examine the genital parts? when the vulva is affected, scarcely have we separated the great lips and the small lips when we meet with the morbid secretion, frequently even the hairs are loaded with it, and in some points in dirty women this matter is concreted, and tends to obliterate the entrance of the genital organs, as in certain cases of ophthalmia we see the eyelids glued together by the palpebral discharge. But frequently the inspection of the vulva permits of nothing being seen, and we must then go in search for the morbid secretion. For that of the urethra, the indicator finger must be introduced into the vagina as far as to a level with the articulation of the first and second phalanx, its pulp being turned towards the symphysis pubis, and brought subsequently from behind forwards in pressing upon the canal. In this manner may be made to come out a drop or two of pus or puriform mucus from the meatus urinarius, provided the examination be made some time after the emission of urine, and the urethra be affected. With a little habit, matter coming from the adjacent parts will not be taken for matter coming from the deep part of the canal.

In examining thus the excretory canal of the urine, while the extremity of the finger compresses it, the dorsal face of the root of the same finger leans upon the posterior part of the vulvar ring, which it depresses, and we then see the vaginal discharge escaping outwards. Frequently, however, an abundant secretion remains, as it were, incarcerated in the canal of the menses, and the superficial or

unwarned observer might be deceived. Indeed, the discharges coming from the deep parts of the vagina may be retained, by narrowness or contraction of the vulvar ring; in some women by a turning backwards of the inferior part of the vagina, which comes to form a kind of cork in the vulva, and finally in some others by certain dispositions of the feculent matters accumulated in the lower part of the rectum; and by the urine in the bladder. I have thus seen many women affected with whites, or with blennorrhagia, who evacuated a great quantity of matter by the vulva, only at the moment of defecation, or of the emission of urine.

As to uterine discharges, which display themselves most frequently by the issue out of the vulva of mucosity more or less purulent, and of which we have elsewhere marked the characters, we cannot ordinarily recognise their presence, but by the aid of the speculum. The same thing is true in those coming from the deep-seated parts of the vagina, and from the periphery of the neck of the womb; in those cases in which the exterior of the uterine neck, affected conjointly with the blind sac of the vagina surrounding it, presents the aspect of balanitis (preputio-glandular inflammation) in the man.

The speculum, of which I have been the first to propose the employment in a general manner, in the study of venereal diseases of the genital organs of the woman, is an instrument, which cannot be neglected, if we desire to employ rational treatment, and to avoid the most serious errors of diagnosis*. The speculum of which I now make use is an opening speculum (*speculum brisé*) of which the valves, bent upon themselves from without inwards, are articulated at the point of their flexion, as in the speculum of my friend, M. Jobert; and of which the articulation, placed upon the points of the instrument that is to correspond to the vulvar ring, permits its two extremities to be alternately opened or shut, without the vulvar ring being itself dilated and painfully compressed against the arch of the pubis, as has been pointed out by the ingenious surgeon of the Hôpital St. Louis, from whom I have borrowed this idea. Each valve of my speculum sustains a branch or handle, bent at a right angle with it, serving to fix or to open the instrument, without the hand of the operator, or of the aid to whom he may intrust it, masking the parts wished to be examined, or hindering the action of the instruments that might have to be introduced into its interior. Further, a graduated stem, furnished with a male screw, and two buttons containing female screws moveable upon it, is fixed upon one of the handles and traverses the other, so that by aid of the buttons that roll upon the male screw, the valves may be held approximated to a suitable degree, and even the degree of

their separation may be known by the scale graduated in lines, and thus the different volumes of the neck that we may be interested in knowing, in the greater part of cases of swelling or hypertrophy, may be measured. For the application of the speculum* the following are the rules that I practise.

The patient is placed upon the edge of her bed, a pillow under the shoulders and under the head, the thighs half bent upon the pelvis, and the legs half bent upon the thighs, the feet resting upon the backs of two chairs placed on either side. The surgeon places himself between the lower extremities, and has no need of an aid, a very important point in certain cases of private practice. The speculum, which may be slightly warmed in cold weather, must be coated with a greasy body. When the organs are narrow, I prefer white cerate, as more tenacious than oil, as not being so soon wiped off, and as permitting the instrument to glide better and with less pain; in other cases I employ oil, which in no way changes the aspect of the secretions desired to be examined, or the surface of the tissues wished to be seen. The valves of the speculum held in the right hand are strongly approximated, I make even the edge of one slip over that of the other, so as to render the extremity of the instrument almost flat. Separating then the great and the small lips with the ring and indicator fingers of the left hand, I depress, at the same time, by the middle finger of the same hand, the posterior part of the fourchette, and of the vulvar ring. This manœuvre, very important in facilitating the entry of the speculum without pain, must be performed in a gradual, but rather powerful manner. Then the extremity of the speculum is presented to the vulva with its handles turned towards the left thigh, and whilst the edge of the extremity of one of its valves rests steadily upon the medius, placed as we have just directed, the other has its flat part applied against the posterior face of the vulvar prominence of the meatus urinarius, beneath which we are about to make it glide, by a see-saw motion without excoriating or wounding it, as frequently occurs in the other methods. However as soon as the vulvar ring has been passed, the most difficult and the most painful part to pass, the speculum is to be directed in the direction of the known axis of the vagina, its valves being more or less separated from one another, accordingly as required, and thus permitting the successive exploration of the vagina and of the uterus, of which the instrument ought finally to embrace the neck. To that end, the speculum must not be, as recommended and practised by some surgeons, of a ridiculous and unproportionate length, and pushed onward into the vagina continually until the neck be caught, a manœuvre that exposes one to wound the parts, and to cause

* See the last memoir of Dr. Ricord, translated by me from the second fasciculus of the *Mémoires de l'Académie Royale de Médecine*.

† These speculums are made by the distinguished instrument-maker Charrière, and cost thirty francs.—A. T.

much suffering, by pressing on the periuterine blind sac. But we must assure ourselves previously by the *touchée* of the position and of the height of the neck, then direct towards that position the extremity of the instrument, recommending, at the same time, the patient, in proportion as it enters, to make no expulsive efforts, which would for a moment impede the manœuvre. Then moving gently forward the extremity of the speculum between the two lips puckered from one side to the other, that are formed by the anterior and posterior wall of the vagina pushed back, and on either side from before backwards, we soon arrive upon the neck, which is recognisable by its smooother and unpuckered mucous membrane, of which the tint frequently differs from that of the vagina. In some cases the thready mucosity that distills, as it were, from its orifice, and is elongated into the vagina, indicates to you the direction to be followed. Finally, if in spite of these indications and of these precepts, you find your instrument in the blind sac of the vagina, in place of continuing to push on, it must be gently made to experience a retiring movement, separating at the same time its valves to seize the uterine neck, after the manner of a ball in the cup and ball*. All the women I treat in my service at the Hôpital des Vénériens are examined according to the method just explained, and never, if there be no contra-indication to the use of the speculum, such as we are about to point out, have we met with any invincible obstacle in using our process, and such as requires another method or another instrument.

The cases contra-indicative of the use of the speculum, at least momentarily, are,

1stly. A too intense inflammation; particularly of the vulva and of the entrance of the vagina.

2ndly. The presence of the hymen membrane, which must be respected in the greater number of cases†.

3rdly. The narrowness of the parts in young

* With these recommendations of Dr. Ricord, it is almost impossible not to succeed, without the slightest injury or even annoyance to your patient on the very first trial. I know that the very first time I tried it, I succeeded, and the second examined in less than an hour twenty to thirty patients, under the direction of M. Ricord, and without the slightest complaint on the part of any of the patients. I have seen others of my countrymen attempt the same without having previously received these instructions, and either fail altogether, or considerably incommode the patient.—A. T.

† I have even seen it readily introduced into the vagina of two pseudo-virgins, who had had connexion and were married, without the hymen being wounded, that membrane being in them elastic and dilatable. Both of them had the clap, and one of them ulcerations in the vagina behind the hymen.—A. T.

girls; and I have no need here of noticing the falseness of the proposition recently advanced in an article published upon *touchée* and the application of the speculum, "*that the genital parts are the more dilatable in proportion to the greater youth of the girls, and that they lose their dilatability in the adult!!*"

4thly. In a more or less advanced age, the vulva-uterine canal becomes less supple, may be contracted universally, or only in some points of its extent, so as no longer to permit, without danger, of the introduction of the speculum.

5thly. During the period of the menstrual discharge, the introduction of the speculum, which is unaccompanied with danger when a woman does not fear it, is at least useless, for the menstrual blood, washing the parts, it is no longer possible to see anything. However, having had occasion to apply it a great number of times, I can affirm that the uterine orifice during the period of the menstrual discharge in women who have not had a child has not been sensibly dilated, and was at least far from admitting the extremity of the indicator finger, as has also been recently advanced in the article upon the *touchée*, which I have already cited.

The state of gestation has not been for me a counter indication; in the greater number of cases where an examination has been necessary, the introduction of the speculum, made with prudence, and in a slow and gradual manner, has not presented more inconveniences than the ordinary *touchée*.

I have mentioned, for the examination of the genital parts, the use of the entire speculum (speculum. plein) of M. Recamier. This speculum is more painful in the introduction, often too voluminous to pass the vulvar ring, at a later stage of the introduction too small to embrace the uterine neck entirely, and does not in all cases permit of the bottom of the vagina being well examined around the uterus. The period of the invasion of blennorrhagia in the woman is most frequently difficult to seize. The greater part of them subject to whites confound the new discharge with their habitual leucorrhœa; and it is only when the blennorrhagia is rather acute, and when it affects more particularly the vulva and the urethra, that they can well distinguish it, and appreciate the period of its origin. Many indeed only become acquainted with their new affection by the reproach addressed to them of having communicated disease. Notwithstanding, when we have been able to procure precise information, we have found that sometimes the discharge manifests itself almost immediately after the action of one of its causes; while in other circumstances, it only occurred after a certain period of incubation, rarely before the third day, and often at a very long time after the connexion, particularly when seated in the deep-seated parts of the vagina, or in the uterine cavity.

Blennorrhagia is rapid or slow in its progress. Commencing with characters of activity it may diminish in a gradual manner, and terminate by a frank resolution at from between fifteen days to a month, as we have sometimes seen it. It may also be abortive at its origin, and disappear by a kind of delitescence; or else again maintain the same state during a rather long period to pass into the chronic state, generally designated under the name of *blennorrhœa*, and which is most frequent in woman; the state of the principal characters of which we have already indicated, and which the disease may assume from its outset, and preserve during its whole duration, or return to the acute stage.

The termination of simple *blennorrhagia* in women takes place, as we have just said, rarely by delitescence, often by slow resolution, and more frequently by a chronic state, almost interminable, which women then veil under the name of whites (*fleurs blanches*), with which it becomes confounded. As to the more serious terminations, such as alterations of the bony system, the mucous system, &c., they depend upon certain forms of *blennorrhagia*, which hitherto have not been well determined, in reference to the diagnosis. Also, if it be easy with a little habitude to distinguish in woman between urethral, vaginal, and uterine *blennorrhagia*, or to assign the characters belonging to these forms, grouped two by two, as sometimes happens, or united altogether; it is certainly impossible to establish for each of them a distinctive character of its intimate nature, which, however, is the important point, the problem that all authors have sought to resolve. They have desired to distinguish *blennorrhagia* from whites, and the little value of the signs given by the authors is well known. Indeed, how distinguish things absolutely similar in form, and differing only, if I may thus express myself, by their intangible essence? Neither the precise seat of the affection, nor the aspect of the discharge, and not even the alterations of the tissues, can lead to a distinction of *leucorrhœa* from simple *blennorrhagia*. The only possible differential sign in some cases may be drawn from a knowledge of the causes, thus admitting, if you will, no whites but those arising under the influence of individual or general causes. All discharges arising under the influence of mechanical, chemical or virulent causes that have acted directly upon the genito-urinary organs will be ranged in the class of *blennorrhagia*, the power of subsequently establishing varieties being reserved. These distinctions moreover, impossible in most cases, owing to the little confidence to be put in the statements of the patients, who deceive themselves or you, might serve to fulfil some indications in the treatment.

The most important part of the diagnosis is to establish whether a discharge be or be not *virulent*.

Of all the phenomena of *blennorrhagia*, those

which have the most arrested the attention, on account of the little value hitherto of the others, in reference to the diagnosis, are incubation, possibility of transmission to a healthy individual, development of consecutive symptoms, production of certain complications, and success of the treatment regarded as specific. Let us examine each of these signs:—

1st. Of Incubation.—Incubation, which, though still ill-determined, seems to appertain to virulent diseases, might sometimes throw light upon the diagnosis; but for those for whom this sign has any value, it is requisite, a rare thing indeed, that the women should have no anterior discharge of whites; and that, removed from the influence of all other causes, they should have had connexion but with one man for a certain time back, a man whom they had also ceased to receive before the development of the *blennorrhagia*; and even then it would remain to be known at what period the discharge manifested itself exteriorly of the vulva, if it had not already occurred on the very day, or on the day after suspicious connexion, in the deep-seated parts of the vagina, or in the uterine cavity, without being effused exteriorly, as we have however seen may occur.

2dly. Of Transmission.—The possibility of communicating a *blennorrhagia* in sexual relation is not proof of the syphilitic or virulent nature of a discharge. The menstrual discharge, simple uterine catarrh, simple vaginitis, as also the simple abuse of coition, may give rise in a man to a simple *blennorrhagic* discharge. A virulent discharge in a woman may also give rise only to a simple *blennorrhagia* in a man. Transmission, however, being a very important point in practice, I shall still dwell upon it for a moment without diverging, I believe, from the question of the diagnosis.

One is very often consulted in society by men affected with urethral discharges, who affirm that the women with whom they have had connexion are in no way unwell. The following is what numerous observations have taught me on this subject:—A perfectly healthy woman may give chancres or clap, and this by communicating to an individual virulent matter deposited in her genital part by another in an anterior coition, without her being herself infected, having in this case, rather frequent in the public women, served only as reservoir. We have admitted besides, with all authors, that by fatigue, or the abuse of coition, *blennorrhagia* may arise in genital parts in other respects healthy; but these discharges, which are rather complainantly named heatings (*échauffemens*) in ordinary language, are much rarer than is generally believed; indeed, women who give *blennorrhagia* almost always present something, as I have elsewhere proved by my researches made with the aid of the speculum. I see every day at my hospital, and in my private practice, women accused of having given

blennorrhagia, and of whom the external genital parts and the entrance of the vulva are perfectly healthy. These women, who frequently have been certified as healthy by practitioners, in other respects able, present constantly deep-seated lesions, which we have elsewhere pointed out; so that whenever a patient presents himself to us with a discharge, you may affirm, without fear of being deceived once in a hundred cases, that the woman with whom he has had connexion is herself diseased. But is it a reason for believing the woman to be syphilitic, because they communicate discharges?—No, doubtless; for in these cases, the contagion is not constant, and does not necessarily arrive; but by position of parts alone a discharge may be communicated, so that a woman presenting one of the morbid conditions I have already described, must not be considered as necessarily venereal, but only as capable of communicating blennorrhagia, which is different. A curious fact should be here mentioned. I have seen some women, who, not believing themselves diseased, and consequently not treating themselves, had communicated for several years back blennorrhagia to almost all the men who had for the first time connexion with them. These women, examined by the aid of a speculum, had all something, either in the vagina or in the neck of the uterus. But what is more remarkable is, that without treating themselves, and without being cured, if a man who had contracted blennorrhagia from them was cured and continued to have connexion with them, he finished by contracting it no longer, *by the aid of a species of climating* (acclimatement). Did an accidental lover intrude, he contracted in his turn blennorrhagia, became cured, and acquired, like the first, the privilege of no longer catching anything; so on for a third and for a fourth. A woman whom I received into my service had repeated the experiment even for five times; a lady's companion in a family in England, she had come to France to be treated. The physician whom she had consulted had found her external genital parts healthy, and hardly believed her stories. Examined by the aid of the speculum, I found her affected with a purulent uterine catarrh, and with granulated ulcerations of the whole surface of the neck of the uterus, lesions, that explained to me the enigma, and of which she was well cured by the aid of local treatment, while all internal and mercurial medications had failed.

Girls, I might also say women, still virgins, at least in appearance, give, under similar circumstances, blennorrhagia. Affected with discharges, whatever may be their causes, they may transmit them. Their integrity of the hymen does not prove that their blennorrhagia is not virulent. Without the physical character of virginity having been destroyed, the vulva may have been alone infected, up to the hymen membrane, which has not been passed. This fact we frequently see in young

girls of all ages, in my nursery service at the Hôpital des Vénériens, and may occur in the adult and at a still more advanced age. I hope I may be permitted, on this subject, to relate a humorous case, which may prove useful to some newly married women. A girl of some fifty years, arrived expressly from the provinces, came to consult me at my house, to know *whether she was still a virgin*. Having the intention to be married, she was very anxious of bringing as a marriage present the proof of her continence. The first question I naturally asked her, was to demand whether she had had any lovers, she answered me yes! I thought then that my patient was mad, or that she was anxious to play the fool with me. But I was undeceived when she told me, that she had never permitted her lovers more than *external connexion*; and that she wished actually to know whether they had not transgressed her limits. She was indeed still physically a virgin. I have had at the venereal hospital a woman, married already for five years, who had had more than one lover, and who was affected with urethro-genital blennorrhagia, in whom the hymen membrane was complete. These cases prove, that when one has contracted clap from a virgin, we must be careful of attributing it always to an ordinary heating, or if you will to irritation, to simple inflammation. The physical signs of virginity not being those of continence, which, as is known, unhappily has none.

Leaving these digressions, which will perhaps appear not altogether devoid of utility, and seeking something more positive in reference to the different diagnosis between virulent discharges and those which are not so, we have had recourse to inoculation, which forms the subject of a memoir, read to the Royal Academy of Medicine*, and we have found that the matter of blennorrhagia, taken from the surface of the vulvar, vaginal, and uterine mucous membrane, when there were no chancres on these, and inoculated by the aid of the lancet, as we shall hereafter make known, has never produced any thing, while matter taken from the surface of a chancre has constantly yielded us a characteristic pustule. We have necessarily concluded, from this experiment, that there is no virulent blennorrhagia capable of giving rise to a chancre, unless it is itself complicated with chancre, and that consequently, whenever a woman has communicated a true chancre to a man, she must likewise be affected with it, or momentarily have had shut up in her organs the matter of chancre, distinct from her blennorrhagic discharge, and deposited by some individual, affected with chancre, in an antecedent connexion.

3rdly. *Finally deprived of this character,*

* The translation of this paper will be sent, —A. T.

the possibility of producing inoculable chancre, there is but one species of virulent blennorrhagia, that which, well observed through the whole of its course, and not being complicated with chancre, of which we can more easily convince ourselves in women, owing to the facility with which the organs are visible, through nearly the whole of their extent, is nevertheless followed by some consecutive symptoms, such as mucous papulæ, &c., and then the presence of these symptoms is the only character capable of giving precision to the diagnosis.

Here I cannot pass over in silence a fact, it is that the mucous papula, or pustule, which for all the world is an incontestable sign of pox, presents a very remarkable peculiarity, namely, that it is impossible to inoculate from it with the lancet, whether one takes the matter secreted by its surface, or that of the discharge that accompanies or precedes it. As to the contagion, by means of connexion, of blennorrhagia, accompanied with mucous pustules, it is far from being constant. The following is what we have observed:—We have sometimes had at the hospital, at the same time, the man and the woman affected with blennorrhagia, accompanied with mucous pustules, but most frequently the two individuals have been affected with blennorrhagia, and one only presented mucous pustules. I have recently taken down, in my private practice, a remarkable case, which here follows. I had treated a gentleman for a chancre of the prepuce; a mercurial treatment had been employed; three months after the cure he was married; before the end of six months he consulted me again, in order to be assured whether he was quite healthy; under such circumstances, I had necessarily to bestow the greatest attention upon the examination I was about to make; the organs of generation were found in the usual state; there existed no trace of primitive ulceration; there was not actually any discharge (the patient had never had any); no consecutive symptom displayed itself, either on the skin or in the bones, or in the throat. Three months after his marriage this gentleman called me to his wife, who, said he to me, had *some big pimples on the parts*. I examined her; I found her three months gone with child, and affected with urethro-genital blennorrhagia, and with a most extensive and confluent eruption of mucous papulæ; she had them from the mons veneris even to the coccyx, and half way down the thighs. I asked her husband if he had continued to have connexion with her; he answered me that he had not ceased for a single day. Well, this gentleman, as at the moment of his marriage, presented no symptom of disease, either primitive or consecutive, his wife must then have been diseased before her marriage, and since that she had communicated nothing to him in the frequent connexions they had had. We have often seen women affected at once with blennorrhagia and mucous pustules. The blennorrhagia and the

mucous pustules could never yield inoculation by the aid of the lancet, while, by this means, with the matter of chancre was produced a pustule, always the same, of which we have elsewhere given the history, and which we shall soon publish. These women communicated to some men blennorrhagia only, or chancres, and to others the two affections at once.

As regards the other consecutive symptoms of blennorrhagia, their history does not appear to me to be as yet sufficiently precisely drawn up, to render them serviceable for the diagnosis.

The complications have scarcely more value; and leaving aside blennorrhagic ophthalmia, on which there is so little unity of opinion, to occupy myself only with buboes, the following is what I have learnt from experiment. In blennorrhagia in the woman the inguinal glands may be inflamed and suppurated, and that more especially when the urethra is affected, but unless there have been chancres of the genital parts, which constitutes another disease, the buboes have never been virulent, that is to say, the discharges, upon which they seem to depend, not being inoculable by the aid of the lancet; never has the pus, furnished by them, been susceptible of yielding inoculation, while the pus of ganglionic bubo, the consequence of chancre, has always produced, by the aid of inoculation, the characteristic pustule.

4thly. We too well know in the present day what confidence to place in specific treatments, to regard their action as decisive, in reference to the diagnosis, so I shall not stop myself to prove their little value. We must then conclude, from all that precedes, that unless consecutive symptoms be present, which must be very well determined, we remain, as regards the diagnosis, in the greatest uncertainty, not being able conscientiously to recognise more than the physical alteration of the parts, and of their secretions, without being able to divine anything of the intimate nature of the disease, or of its essence, if we may thus express ourselves; and finding oneself reduced to determine the existence of urethritis, of vaginitis, or of uterine catarrh without being able to say anything more, for beyond that all is but probability, and most frequently error.

If the diagnosis be thus far from certain, the prognosis must itself be very vague, not indeed when there is a question of foreseeing the issue of an inflammation, of a urethritis, of a vaginitis, or of a uterine discharge, but when we foresee the consequences of a blennorrhagia, as to consecutive symptoms, and the possibility of its determining constitutional syphilis, or general infection.

In the next article I shall treat of the complications and of the treatment.

ALDERSGATE-STREET DISPENSARY.

A MEETING of the Medical Profession was held on Saturday evening, at the Freemasons' Tavern, for the purpose of adopting some public measures in approbation of the conduct of the late medical officers of the General Dispensary, Aldersgate-street. The meeting was very numerous attended by all branches of the profession.

Dr. Elliotson took the chair, and, after a modest apology for his incompetency, proceeded to explain the purpose for which the meeting had been called together. There were two subjects to which their attention was to be directed, namely, the regulation recently adopted by the governors of the General Dispensary in Aldersgate-street; and the consequent resignation of the medical officers. The effect of the regulation to which he referred was neither more nor less than putting up the medical offices for sale to the highest bidder. Surely it would be better not to have the farce of an election at all under such circumstances, but that the situation should be openly set up for auction on a certain day; and if the medical offices were thus disposed of, so ought also the treasurership, and all other honorary and responsible places. Such a system certainly could not benefit the charity, while it would lower the character of medical men. Horace well said—

"Ipse tibi melius suadet, qui ut rem facias rem,
Si possis, recte; si non, quocunque modo,
rem?"

It was bad to look to money alone. There should be amongst medical men a feeling of character and dignity, and love for their profession, and if that were taken away the profession itself must be injured. With regard to the resignation of the medical officers of the dispensary there could be but one opinion in the profession—(hear, hear). If it were said that the rule which had recently been adopted was only the restoration of an old law, he replied that that was of no consequence.

When they had gained one step towards the reformation of abuses they ought not to lose it, but to maintain their ground, and, if possible, to go forward. If this was the first time medical men had resigned under such circumstances, the greater was their honour, and it was the duty of the whole profession to support them—(hear, hear). He had that morning received a letter from Mr. Costello, stating that at a large meeting at Colchester, resolutions had been unanimously passed in approbation of the conduct of those gentlemen, and that at Ipswich similar resolutions would have been adopted but for a report that the medical officers had accepted office again. He trusted that in the course of their present proceedings no personalities would be indulged in—no motives attributed to those who had acted in a manner of which they did not approve, but that the meeting would set an example which would conduce to the respectability of the profession.

Dr. J. Johnson, in submitting the first resolution, insisted upon two propositions, that professional merit alone should entitle men to professional offices, and that the candidates should have a fair arena for competition, not checked or influenced in any degree by wealth. It was to reprobate and stigmatise the venal law which would subvert those principles that the meeting had assembled, and he trusted their verdict would consign it, not to oblivion, but to the execration of every honest mind. He then mentioned an instance in which an office had been obtained in a charitable institution by the payment of seventy guineas, which entitled the individual to as many votes. In consequence of the introduction of this practice, the institution was rapidly falling into decay, and would have been completely ruined but for the renewal of the old salutary law that no governor should be entitled to a vote unless he were of three months' standing. He moved a resolution, declaring the opinion of the meeting that in all "Insti-

tutions for the charitable supply of medical and surgical aid to the poor, it is discreditable to the institution; and detrimental to the poor, that the medical and surgical offices should be subject to laws which render them places of purchase and pecuniary contest."

Mr. Pettigrew said he happened to be a life governor of the institution which had been referred to by Dr. Johnson, and he believed it was 700 instead of seventy guineas that were paid for the office in question. From his knowledge of the manner in which the duties of the officers of the Aldersgate-street Dispensary had been discharged, he regretted, on account of the poor objects of the charity themselves, the circumstances which had occasioned the resignation of the medical and surgical officers. He believed that no institution was fortunate enough to possess more able, if so able, officers. He believed also that this was the only dispensary with which there was a medical school connected. From his knowledge of the benefits which such an institution must confer, he had ventured to suggest to an illustrious individual to become the patron of it, and it was a source of no little pride to him that that illustrious personage had concurred with the medical officers recently belonging to that establishment in their estimate of what was due to the character of their profession—(hear). He had great satisfaction in seconding the motion.

The resolution was then carried unanimously, with one exception in the person of a very young gentleman, rumour says an apprentice of Mr. Stanley's, who explained his opposition by saying that he understood some of the medical officers were again canvassing for the situations.

The Chairman said that this was not the case, and reminded the youthful dissident that even if it were, it did not affect the principle of the resolution.

Dr. Haslam said the practice which they had met to condemn was not a

new one, but it ought to be discontinued. In the year 1793 he was a candidate for an appointment in a dispensary, and had collected 130 out of 250 votes, but his opponent said to him, "you need give yourself no further trouble, for I mean to buy the place"—(a laugh). And accordingly on the day of election the gentleman put down 500 guineas, and had 1000 in reserve if they had been necessary to secure his appointment. He knew of two more instances of the same kind. In one institution (which had since perished, in consequence of such practices), it was made a rule that the physician should be changed every three years, because it was calculated, as a commercial speculation, that in that time a doctor was worn out. A surgeon, it was considered, might last five years—(laughter). He moved that "The cordial thanks of the profession are justly due to the late physicians and surgeons of the General Dispensary in Aldersgate-street, for their honourable and independent conduct, in resigning their appointments rather than sanction the re-introduction of a law involving the obnoxious principle condemned in the previous resolution."

Dr. Waller seconded the resolution, and it was carried unanimously.

Dr. Uwins said it was the duty of every member of the profession to study by every means in his power to promote its respectability, and he moved "That the various members of the medical profession, residing in and near the metropolis, be requested to affix their names and places of abode to the foregoing resolutions."

Mr. Smith seconded the resolution. It was time the profession should emancipate itself from the commercial slavery in which it was involved, and should stand upon its own basis, freed from the influence of petty tradespeople and individuals of that description, who—(hisses). If he had been suffered to finish his sentence, he was sure his observation would not have given offence. He did not despise any rank of life, but objected to that

sort of influence which was inconsistent with the high tone of feeling, and the integrity of conduct which ought to distinguish the profession.

Dr. Elliotson observed, that he did not consider Mr. Smith's remarks as offered offensively to any class of persons, but meant that the persons to whom they applied were not competent to manage professional matters.

Mr. Pettigrew then moved, "That Dr. Johnson do take the chair."

On the motion of Dr. Roots, thanks were then voted to Dr. Elliotson, and the meeting broke up.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, October 14, 1833,

WILLIAM KINGDON, ESQ., President,
in the Chair.

Bad Rice the cause of Malignant Cholera, Yellow Fever, & Dysentery.

A SPANISH physician, connected with the court of Spain, stated, that he had communicated to his government the result of his inquiries in this country, on the cause of cholera. He had noticed Dr. Tytler's opinion, that deteriorated rice was the predisposing cause, which he denied. He then read a translation of his despatch to that purport. He also denied, that Bengal rice was the cause of cholera at Cadiz, as the law prevented its importation into Spain. He mentioned, that the rice, used at Cadiz, was furnished from Valencia. He likewise denied that the epidemic of the troops at Cadiz was attributable to Bengal or any other kind of rice.

Dr. Tytler replied, by quoting extracts from a Calcutta newspaper, which went to show, that rice was sold at Cadiz, during the epidemic, at two shillings per hundred weight. He read a copy of a letter from a Roman Catholic clergyman, the Rev. Mr. Murphy, who was prior of a convent, by which it appeared, that the writer and ten of the inmates of his establishment were seized with the

epidemic from having eaten rice. He also read a copy of a document, to prove that the Spanish troops had severely suffered from the same cause.

Dr. James Johnson rose to order, and said that the epidemic alluded to was yellow fever, in which the fluid, ejected from the stomach, was black and not white, as in the late epidemic cholera, and, therefore, that Dr. Tytler was losing sight of the question before the meeting, which was, that rice was the cause of malignant cholera.

The President observed, that it appeared to him, Dr. Tytler was in order in replying to the objections urged to his doctrine by the Spanish physician, but he was in the hands of the society, and he would regulate the discussion as they (the society) thought proper.

Dr. Tytler resumed, and observed, that Dr. Johnson and others were contending about names, but he was speaking of disease as it existed. He did not call the disease at Cadiz yellow fever or cholera, but he proved beyond doubt that it was ascribed to rice. Dr. T. then exhibited specimens of wheaten flour, rice flour, bad rice flour, and, having intermixed them, he defied any gentleman in the room to show how bread, made of the mixture, could be proved to contain rice. It therefore followed, that adulterated bread of this kind might be in general use in London and escape detection, even at this moment.

Dr. Johnson remarked, that Dr. Tytler had accused him of having been the cause of all the deaths caused by cholera, both in India, in this, and in all countries, by having mentioned in his work on Diseases in Tropical Climates, that the facts adduced by Dr. T. were not proved, and that his conclusion was dubious. Dr. Tytler had said, that his, Dr. Johnson's, authority was so much respected in India, that being opposed to his views, the profession refused to entertain or receive his conclusion. Dr. Johnson then read two official reports, furnished by Mr. Cohen and Mr. Ha-

milton, two army surgeons to the medical board at Madras, by which it appeared that the soldiers, affected with cholera, after landing, had not used any description of rice whatever.

Dr. Tytler rejoined, that though it was dangerous for him, as an officer under the Honourable East India Company, to comment on the document furnished by Dr. Johnson, yet he would not shrink from the task, as his object was the elucidation of truth, and he would, in the face of his medical brethren, do his duty, whatever might be the consequences. He hoped that no individual would ever be treated in the manner he had been. He had only to observe, with regard to Dr. Johnson's official reports, that they were furnished by young surgeons, who had just arrived from Europe, and as the inquiry would expose those who had supplied the provisions to the troops, these individuals dare not censure them. In fact, cart loads of such documents would be furnished to-morrow if called for, and were no evidence whatever. He would put it to the good sense of the society, whether the government were right in applying to surgeons who had just arrived from Europe, and not to him, who was the oldest surgeon in India, and who had first seen cholera at Jessore, and traced it to rice, for information as to the cause of the disease. But he would read a document to prove that rice was the diet of the troops; which he did. He concluded by stating, that little, indeed no reliance, could be placed on official documents.

Mr. Marsden remarked, that he had some experience in treating cholera in this metropolis, that he made inquiries as to the use of rice, and ascertained that it had not been employed in one case out of ten. He did not believe that rice was the cause of cholera in this country.

Mr. Headland wished to make a few observations on the question before the Society; and having taken some trouble to ascertain how far rice could be considered a cause of cholera,

he thought it his duty to inform the Society of the result of his inquiries. He learned, from sources upon which he placed the fullest reliance, that rice had been mixed with flour from 1816, when the wheaten crops failed in this country, to 1823, but in very small proportion. Since the latter period such admixture was not made, because flour was cheaper than the worst and most deteriorated kind of rice. The best flour was now to be procured at one penny farthing per pound, the worst rice at one penny halfpenny. The bakers had no interest in mixing both under such circumstances. He thought it consonant with the honour of the Society to disabuse the public mind of erroneous conclusions.

Dr. Tytler felt himself called on to confute the arguments of the gentleman who spoke last. He felt obliged to him for the information he communicated, which was certainly important. He said that bread was mixed with rice from 1816 to 1823, and at this period cholera was prevalent in this country, according to Dr. Johnson's review of Dr. Ayre's work on cholera.

Dr. Johnson rose, and said that it was unfair to attribute to him every thing that appeared in his Journal, as he was not the writer of all the reviews.

Dr. Tytler maintained that the words were Dr. Johnson's, and not Dr. Ayre's, and that cholera had prevailed in this country.

Mr. Langford claimed the indulgence of the Society while he offered a few proofs against Dr. Tytler's conclusions. He had visited most of the workhouses in this metropolis, and ascertained that rice formed but a small portion of the food of the inmates. In Clerkenwell no rice was used, and yet there was cholera. He had written to Bilston, and would read an extract from the letter of the Rev. Mr. Lee, which proved that rice had nothing to do in the cause of the disease. He also read a letter from Mr. Ollier, the surgeon to the New

Bailey Prison, Manchester, to the same effect. He also adduced his own experience as medical attendant at the Cholera Hospital, Manchester.

A gentleman requested to be heard for one moment before the Society adjourned. He had this day received a letter from a lady in the country, in which the writer stated that she had reared poultry on the worst kind of rice, and that the fowls were superior to those fed in the ordinary manner.

The President then adjourned the Society.

[We have heard the three discussions at this Society, in which Dr. Tytler took a prominent part. We unquestionably consider the Doctor entitled to great praise for the ability, wit, and independence with which he defended his opinions. We think, however, he is in error, when he argues that bad rice is the cause of cholera. Ten thousand proofs disprove this conclusion. Thousands have had cholera who never tasted rice. Bad rice, like bad farinaceous aliment of any kind, will derange the stomach and bowels, or, to speak technically, the digestive tube. Thus far Dr. Tytler has gone, but no further. We do him but justice to state, that he possesses an ability to reply, a readiness to expose the weakness of his opponents, and an enthusiasm in maintaining his conclusions, which show him to be a physician of mind, of great experience, and of high talent. He has certainly proved that bad rice will disorder the stomach and bowels, but in our opinion nothing more.

THE

London Medical & Surgical Journal

Saturday, October 19, 1833.

THE LATE ALDERSGATE STREET
DISPENSARY.

THE character and management of this venerable Institution have been so much altered, under the govern-

ment of the present committee, that, in the public eye, it must be considered as defunct, *stat nominis umbra*. The rotten trunk, which will by-and-by, unless it falls under the late shock, fill the air with the stench of its fungous medicals, scarcely deserves our notice; and hearty haters as we are of jobbing and quackery we should not be tempted to comment upon the noisy pranks which distinguished the meeting of Governors on Monday last, were there not involved in the dispute the permanent interests, not only of the medical profession, (a matter of no trifling public importance,) but also of the charitable institutions of the metropolis, which, bating some trading Samaritans, are in the main supported by genuine British humanity, and which it is grievous to see abused. Of the particulars of that meeting our readers must be aware from the daily press. An effort was made by some of the oldest and most respectable Governors, from the most disinterested motives, springing solely from the integrity of their own breasts, to allay the storm, and to give an euthanasia to the discord, which has prevailed for weeks past, to the manifest ruin of the charity. This preliminary to peace, by restoring things *in statu quo*, was rejected; and a Mr. Hewett (we should like to know if he is the friend and legal adviser of Mr. Wyatt, who has distinguished himself from the rest of the profession, by starting as a candidate for one of the vacated offices) signalled himself as the Lord of Misrule. He was well supported by a Mr. Anderton, whose

name by-the-by is to be found, unless we are grievously mistaken, among the last cluck of Governors, that the Committee has hatched for its last job on Monday, and it is a question whether he is not the friend and legal adviser also of Dr. Whitsed, alike distinguished as his compeer, Mr. Wyatt—*par nobile fratrum*.

This worthy seconder argued, that because other charities were exposed to the like abuse as that against which the late eminent medical officers of the Aldersgate Street Dispensary have so spiritedly reclaimed; therefore, &c. This is what we beg leave to denounce as medical pettifoggery. But a word by-and-by upon the principle. This same gentleman, out of pure gratitude, seeing he never had occasion to employ any other than a general practitioner in his life, would have the appointments thrown open to that class of the profession. But we beg to hint, whether, lawyer as he is, he was altogether prudent in stating that "the *Institution* had been put to considerable expense in advertising to refute the calumnious attacks which had been made on the committee." A very charitable and lawful use, forsooth, to put the money of the subscribers to; let us hope, however, that the new batch of subscribers will at least defray this useless expense. It is needless to perpetuate the names of the gentlemen who were called to order for their disorderly conduct. But to wind up the affair, after the asterisk of the Committee, "who did serve the drugs," had spoken a great deal and "meant nothing," a

Mr. Bishop, with a true sense of ridicule, put the whole matter to the test, and without laughing himself, proposed "that the medical offices should be put to auction." The motley assembly were not as dry humourists or as cool reasoners as Mr. Bishop, and actually burst out laughing at the naked proposal of the pure consequences of their proceedings.

The result of this meeting must be painful to the real friends of the charity, whose contributions are abused. The late medical officers have nothing to regret in a measure in which they took no part; and with the warm sympathy in their struggle for professional respectability, which has been shown to them by their brethren, they may still boldly and fearlessly appeal to the ordeal of public opinion.

We must now say a few words upon the real motives of all these strange proceedings. There are no persons more willing than ourselves to denounce the practice of nepotism, the besetting sin of all oligarchies, and be they sincere or not, we heartily join in the wishes of the Committee to counteract any attempt to dispose of the medical appointments of the institution by family compact. Abuses of this sort are to be found, flourishing with the vigour of weeds, in every one of our hospitals and public charities. We have our own ideas upon the mode in which the medical appointments of public institutions should be filled up. It is a subject we have in view for a future occasion. But, admitting for

argument that the medical body had acquired too much influence in the appointment of their successors, was this evil to be remedied only by the introduction of the unmitigated mischief of actually selling the health of the poor to the man of longest purse; and of actually shutting out the laborious, the scientific, and experienced practitioner from all chance of success, by rendering his gratuitous services to the poor an introduction to the public, unless he had that at his command which few, who have ever acquired any eminence in the profession, have commenced with possessing? But this is not all.—It is not a mere question or wrangle about the appointment of the medical officers that is before the public scrutiny. It must be remembered, and it will not be forgotten, that the Committee are charged with “many glaring improprieties and acts of favouritism, especially connected with the management of the charity.” There is such a thing as a traffic in letters of admission as well as in drugs. It may be very convenient for a grocer, tallow-chandler, or baker, to wrap his sugar, candles, or flour in a piece of paper so useful to his customers as a letter of admission. Some forty or fifty patients on the books of the charity at the expense of a guinea a year is a very capital device for popularity. It does not matter whether all this be contrary to the laws of the charity. Let the charitable donor only be a committee-man, and the whole thing is made easy. Abuses of this sort, and of every other sort, in the ma-

nagement, beside the drug treasurers, were exposed with too much fidelity by the medical officers. We are tired of expounding the pranks of this self-defending committee. With their stations in life it would ill become us to quarrel; and were they men who had the public good, and not their own selfish motives in view, they might be a useful check upon the management of the Institution. The abuses here pointed out will thrive much better under a medical body, enslaved to the Committee, who dare not speak out: but it becomes a duty as imperative as charity itself upon the great body of the Governors, who cannot be infected by sordid motives, to consider, upon their next annual payment, whether they will prolong the reign of a set of men, who

“ — dressed in a little brief authority,
Play such fantastic tricks before high heaven
As make the angels weep.”

MEETING OF THE MEDICAL PROFESSION AT THE FREEMASONS' TAVERN.

THOUGH this meeting was extremely crowded, and was about 500 in number, besides many who could not gain admission, still the hospital physicians and surgeons of the metropolis, with three exceptions, were absent. Dr. Elliotson, Dr. Roots, and Mr. Pettigrew were the only hospital attendants. Dr. Haslam, Dr. Johnson, Dr. Uwins, and ourselves were the only Members of the College of Physicians who were present. The meeting was large and respectable; it was princi-

pally composed of highly respectable general practitioners, who, in accordance with the spirit of the times, stood forth to condemn a corrupt system, though it is tolerated in almost every hospital and dispensary in and about the metropolis. The hospital and dispensary medical officers were therefore absent, because they could not join the meeting in correcting the dangerous and villanous abuse of bribery and private intrigue in the election of medical officers. There is scarcely a physician or surgeon, attached to an hospital or dispensary in London, who has not obtained his appointment through interest, vote-making, or intrigue, and not one on the grounds of knowledge, experience, or eminence. Such individuals could not come forward, though every one of them will declare, privately, that the manner in which medical elections are conducted is bad. These persons are erroneously called the heads of the profession, and have not spirit enough to oppose corruption, but when their brethren do so, are so jealous that they skulk into some hiding place, and refuse their co-operation. The evil to which we refer can only be prevented by a public examination of candidates for medical offices before a competent medical jury, or what is designated *concours* in France. This would be the true test of competency; but it cannot be introduced into practice in this country for a long time, unless medical reform be carried to the fullest extent by the legislature. Until then, the poor in hospitals and in dispen-

saries will be treated as they now are in general by students, young surgeons and physicians, who have little, if any practical experience. We have often said that clinical experience is not sufficiently enforced in this country; the attendance of the majority of students at such institutions is a farce,—they acquire information from books; and if they can answer by rote like parrots, they receive degrees and diplomas. These documents are no proof whatever of practical experience,—they merely show that the holders of them, in the opinion of those who grant them, have studied medicine. It would be as absurd to suppose that young barristers just called to the bar would be equal to a Scarlett, a Sugden, or a Wetherell in a weighty lawsuit. This is the error into which the Committee of the late Dispensary in Aldersgate-street have fallen,—which men of mind or sense would carefully avoid. Self-interest is inherent in all men; and therefore governors and medical officers will, whenever they can, serve themselves and their relations at the expense of justice, humanity, and professional dignity.

THE ROYAL COLLEGE OF SURGEONS.

WE understand from the best authority that the Court of Examiners and Council of the Royal College of Surgeons have determined to pull down the building in which they now assemble, as it is too limited for their museum and library.

MEDICAL REFORM.—THE COLLEGE OF PHYSICIANS.

WE have been informed on authority upon which we can rely, that Sir Henry Halford, the perpetual President of the College of Physicians, has been in the habit of earwigging Lord Melbourne very frequently within the last few days. Sir Henry has also visited the universities of Oxford and Cambridge, in which there are no medical schools, and no *examination for the degree of Doctor in Medicine*, to confer with the renowned medical professors of those places on the best mode of gulling the government and the public into the belief that there are not such professors on this side of the Ganges, and that their doctors only are worthy of the Fellowship of the College. Sir Henry will learn to his misfortune, before six months, that he may quote his favourite Shakspeare,

"Farewell, a long farewell, to all my greatness."

The age of humbug is gone by. A reformed parliament will and must change the laws relating to the conservation of public health, and the Ministry, the Universities, with the College of Physicians, cannot stay the course of right and justice.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Amputation of the Thigh near the Hip-joint, by Mr. Lawrence.

ON Saturday, October the 12th, Mr. Lawrence performed amputation of the thigh near the hip-joint, in a young woman, *ætat.* 25. The history of this patient's case is extremely interesting. She originally laboured under severe disease of the knee-joint, for which it was found necessary to remove the limb above the

knee. Soon after the operation the stump was attacked with most excruciating pains, which rendered the patient's life so truly miserable, that, in accordance with her earnest entreaties, Mr. Lawrence proceeded to amputate the stump. In the operation Mr. L. was assisted by Messrs. Earle, Stanley, and Skev.

The amputation being so high up, the adjustment of a tourniquet was impossible, and, accordingly, Mr. Stanley compressed the femoral artery by means of an instrument. Mr. Lawrence, with a large amputating knife, in one sweep, made a circular division of the integuments, and having put back the flap, he dissected the deep-seated parts with a smaller knife. The hæmorrhage during this part of the operation was rather considerable. Mr. L. then drew the saw across the bone, which suddenly snapped, and gave way in a manner that proved its structure was somewhat altered. During the operation the patient became extremely sick, and vomited the entire contents of her stomach. Previous to her being removed she became very faint, and large quantities of wine were administered, which she drank with avidity. The usual number of arteries were tied. The surface of the wound was then cleaned, and the edges approximated by means of large broad stripes of adhesive plaster. The patient was then removed to bed. Immediately after the operation Mr. Lawrence came forward, and made the following remarks on the case.

"Gentlemen,—In the case in which you have just seen me operate, the thigh was formerly amputated for disease of the knee-joint. The stump, as you perceive, healed remarkably well, but the amputation was succeeded by the most violent pains in the stump. The patient could not bear the least touch on the stump, which became endued with the most exquisite sensibility—a sensibility which rendered her existence truly miserable. The pains in the stump were evidently neuralgic, and they were attended with hysteria. She complained of agonising pains extending from the stump upward along the abdominal muscles, as far as the axilla; indeed, so great were these pains along the abdomen, that it was for a time supposed that the patient was labouring under acute peritonitis. She came into the hospital determined at all risks to endeavour at gaining some relief; even death, she said, would be preferable to the miserable life which she was leading. Since her admission, last summer, every means were resorted to, which were at all likely to afford relief. Leeches were applied to the stump: blisters were also used. Vesication was produced by means of nitrate of silver. Warm and cold applications were used. Internally we gave her opium in large doses, and also sulphate of quinine and carbonate of iron. All these failed; the patient still continued to suffer the most dreadful and unremitting pains. She then requested me to amputate the stump—a measure which, in a surgical point of view,

was not demanded, but to which, in consequence of the earnest entreaties of the patient, and from a hope that relief may be obtained by the operation, I have acceded.

"Now, gentlemen, there can be no doubt of this poor woman's sufferings arising from the state of the nerves produced by the former amputation. Our friend Mr. Langstaff has several morbid specimens of stumps, in which the state of the nerves was materially altered. He has published a very interesting account of some of these specimens in the 16th vol. of the Medico-Chirurgical Transactions. After amputation, large bulbs sometimes form on the extremities of nerves. In the operation which I have just performed, I cut away a large portion of the ischiatic nerve, above the spot where I performed amputation. I also removed a portion of another nerve. I trust these steps will be available in affording relief to this poor creature. We have not yet had time to make an examination of the stump I have just removed, but it shall be carefully examined and displayed for your inspection."

ST. GEORGE'S HOSPITAL.

Calculus Vesicae.—Lithotripsy by Baron Heurteloup.

James Newton, æt. 56, was admitted a few weeks since, under the care of Mr. Brodie; with stone in the bladder. He had some years since, we believe, been under the care of Baron Heurteloup, who had broken down a stone and relieved him; and Mr. Brodie requested the Baron again to take charge of him whilst in the hospital.

The first operation was performed on Friday the 11th. The man was placed on the *lit rectangle* in the operating theatre; the bladder was injected, and the stone seized and broken into fragments. The Baron stated the stone to be a flat one. The man returned to bed. There was but little consequent fever, and the patient's general health continuing good, the second operation was performed on Tuesday the 13th.

Previous to commencing the operation, the Baron (through an interpreter) addressed the gentlemen present, remarking, that on the last operation he had detected the stone to be a flat one, and had broken it into fragments of greater or lesser size; some of these had unfortunately been thrown away, but those the patient had passed within the last twenty-four hours had been kept, and had come away nearly in the state of powder; within the last three hours, also, the patient had passed larger fragments, and, in sounding the bladder for the second operation (continued the Baron), much caution and care is requisite, lest there should be a small fragment of stone in the canal of the urethra at the time, which by unnecessary violence may lacerate the lining mucous membrane.

The patient was then placed upon the *lit rectangle*, and the urethra having been carefully sounded, the bladder was injected, and the *brise pierre* introduced. A fragment of stone was readily seized, which the Baron stated to occupy a greater space between the anterior and posterior branches of the instrument than the whole stone did before being broken. The instrument was fixed, and a few smart blows with the hammer were immediately struck upon it; the instrument was withdrawn, and between the branches were numerous fragments of stone reduced to a fine powder, which the Baron showed to those around him. This was scarcely done, when the patient, who was still lying on the table, was seized with general shivering and trembling in all his limbs, spasmodic difficulty of breathing, &c. This naturally drew the attention of all towards him, fearful lest some untoward accident should happen. The nervous symptoms, however, soon subsided, the man's face became flushed, and the frontal vessels appeared swelled, even at the distance we were from him; he complained of intense pain at the back of his head, and was therefore removed to bed. The Baron stated, that these symptoms were purely referable to nervous irritation, that he could give no reason for them, and they had not happened to the man before. A bystander observed, that the patient had taken no food that morning, which the Baron remarked was quite a sufficient reason to account for all the symptoms. Mr. Brodie said, that he hoped the symptoms would turn out to be nothing more than what they had all seen. He had frequently known the same thing happen after passing a bougie.

With reference to the operation of lithotripsy both Mr. Brodie and Mr. Keate are, we believe, very sceptical, as to the superior efficacy of it over lithotomy, and this could be plainly seen in the Baron's conduct towards these gentlemen. His anxiety in pointing out to Mr. Keate all the steps of the operation, and his asking Mr. Brodie afterwards, "*êtes vous satisfait*," plainly proved this. It appeared to us, that in breaking up the fragments of stone more force was used with the hammer than the case warranted.

Mr. Brodie's opinion is, we believe, against it. The common operation of lithotomy may be employed in many cases, where lithotripsy is unadvisable; nor do we believe, that the number of cases cured by the latter operation (although they are in general picked ones) averages above those cured by lithotomy. When first the operation was performed by Civiale in Paris, as long as it was confined to private cases it was generally successful, but on its being performed on patients in the public hospitals, the deaths, we believe, were as one to five.

13th. Seven P.M. The patient had a convulsive fit at five P.M.; he was immediately bled to $\frac{xx.}{}$, and an assafoetida enema was administered, since which he has had no return

of the spasm, and has passed a small quantity of turbid urine; pulse 90; tongue white and furred. It was also stated, that he had passed some blood by the urethra, but on this point we could not perfectly satisfy ourselves.

On Thursday, October 10th, two operations were performed in this hospital. The first, which was performed by Mr. Hawkins, was the division of adhesions, which had taken place between the gums and cheeks in a child, about seven years of age. Mr. H. remarked, in reference to this case, that the adhesions resulted from severe inflammation, caused by an improper exhibition of mercury; the child was completely lock-jawed, and could not open her mouth; by dividing these adhesions he trusted there would be no recurrence of these bad symptoms. There was very little hæmorrhage.

ST. THOMAS'S HOSPITAL.

Chorea successfully treated with Carbonate of Iron.

CHARLOTTE CORNELIUS, aged 18, was admitted into Elizabeth's ward on the 22d of May with chorea, which came on after a sudden fright seven weeks before, and had been getting worse ever since. She had been for some time in one of the large hospitals in this metropolis, but, deriving no benefit from the treatment there employed, she left it and came to St. Thomas's. She had been taking a variety of medicines, and, amongst others, carbonate of iron in small doses. At the time of her admission the involuntary action of the muscles was so violent, that it was with difficulty she could be retained in bed; her limbs and face were incessantly and violently distorted; she could neither eat nor speak but with the greatest difficulty, and was quite unable to put out her tongue. There was no headach, nor was the general health so much affected as might have been expected from the time the disease had existed. She had only menstruated once, about eight weeks previous to her admission, just before the accession of the disorder. Bowels costive. Dr. Roots saw her on the 4th, and ordered her head to be shaved, and a cold lotion to be applied. Milk diet.

Ferri carbonatis, 3 ij. 6ta quaque horâ.

8th. The patient was better, and could put out her tongue; but the spasms had been so violent since her admission, that it was found necessary to strap her to the bed, to prevent her from throwing herself off. The bowels were very much confined, and ol. crotonis mj. was ordered to be taken every morning. A pint of beef tea in addition to milk diet.

Ferri carbonat. 3 iij. 6tis horis.

11th. The croton oil acted freely upon the bowels; but it was only given once, as the

spasms were rather worse, and it caused so much prostration that an ounce of wine was ordered to be taken three times a day.

Ferri carbonatis, 3 iij. 4tis horis.

15th. The wine occasioned great heat and excitement, and was only given three or four times. The chorea was however better.

Ferri carbon. 3 iv. 4tis horis.

18th. Better. There was a troublesome cough, for which tinct. hyoscyami grt. xxx. 6tis horis were ordered.

Cont. Ferri carb.

22d. Gradually improving. The patient continued to take the tincture and the carbonate till the 25th, when the dose of the latter was increased to five drachms every four hours. The patient was much better, being able to sit up, feed herself, and walk a little.

29th. *Ferri carbonat.* 3 vj. 6tis horis.

July 1. Was alarmed by seeing a patient in an epileptic fit, and much worse in consequence; she soon however got better.

5th. *Ferri carb.* 3 vj. 4tis horis.

Tepid shower bath daily.

Ext. hyoscyam gr. v. 6tis horis,

as the cough still remained.

The patient gradually lost the involuntary action of the muscles, but those of the face continued to be affected some time after the symptoms had subsided in other parts of the body, causing momentary and ludicrous expressions of mirth in her countenance. On the 29th, the dose of the carbonate of iron was increased to seven drachms, which she continued to take till the 10th of July, when she was discharged perfectly well.

Chorea.

John Moulder, aged 16, a sawyer, of pale, and somewhat strumous appearance, caught cold three months ago from bathing, and was seized two days after with a neuralgic affection of the right side of the lower jaw. This soon went off, but returned almost every morning for the space of two months. There was now and then a slight headach with giddiness, but not sufficient to prevent the patient from working. Three weeks ago the headach and giddiness became much worse, and he then began to observe "a catching" of the muscles of the right arm, which soon extended over the whole of the right side, and ultimately over the whole body. The headach and giddiness then became better, but have returned several times since, together with the pain in the jaw.

On the day of his admission, July 4th, the contraction of the muscles was so violent, as entirely to prevent the patient from feeding himself, and almost from eating, speaking, or sleeping. Every voluntary muscle seemed

affected, and he was continually writhing and grimacing in a most extraordinary manner. The spasms were not attended with pain, but only with a feeling of great fatigue. Pulse natural; appetite good; tongue clean; skin cool; bowels rather confined. Mr. Stone saw him and ordered—

Ol. Ricini, 3 ss. stat. et rep. si opus sit.

Ferri carbon. 3j. 6tis horis.

House diet.

5th. Bowels have been opened by the castor oil, but the patient is rather worse, and has had no sleep. Dr. Elliotson saw him and ordered—

Ferri carbon. 3 ss. 6ta quâque horâ.

6th. Mane: Became suddenly so much worse as to require force to keep him in bed for a quarter of an hour, and at the same time had a return of the pain in his jaw. This was followed by three hours' sleep, during which he was perfectly quiet. Vespere: The spasms are so violent, producing opisthotonos, that the patient, with his own consent, has been strapped to the bedstead. Though the appetite is good, he is able to take only a very small quantity of food, and it is with great difficulty that the medicines are given. He can only speak in monosyllables, and then does so by a sudden effort. There is an eruption of curved red lines on his hands and feet, with a sensation of smarting and heat in the parts.

Ferri carbon. 3 ss. 4ta quâque horâ.

7th. Still obliged to be confined to his bed, though he is somewhat better. Has taken the medicine regularly. Pergat.

8th. Vespere: Bowels open by castor oil. The contortions of the body were so violent, that he could scarcely be held on the water closet, and nearly sprung from the arms of the men who were conveying him to bed. Pergat.

10th. Is much better; can speak and eat with less difficulty.

12th. Is improving rapidly; the affection almost confined to the face and upper extremities. Pergat.

13th. There is an eruption of boils, to which the patient has been subject, on different parts of the body; a large one on the chin, and two behind the ear.

15th. Continues to take his powder very regularly in treacle, and can now speak much more distinctly; sleeps well, and has been out walking in the square of the hospital.

22d. The patient has continued to take the carbonate of iron every four hours, and has been progressively improving. The spasms have entirely ceased in every part of the body, except in the face, where there still remains a slight twitching of the muscles,

The patient took the medicine till the 30th, when he was discharged quite well. It was occasionally necessary to administer a dose of castor oil during the progress of the cure; but

this was required only two or three times, as the treacle in which the carbonate of iron was administered kept the bowels sufficiently open.

MISCELLANIES.

The following gentlemen were this day elected office-bearers of the Faculty of Medicine at Glasgow:—J. P. Glen, Esq., President; Mr. T. Lightbody, Treasurer; James Lyle, Librarian; W. G. C. Clark, Seal Keeper. Directors—Messrs. J. Buchanan, W. Moffat, J. Dick, J. Anderson, W. Buchanan, H. Clark, A. Adam, and D. Taylor. Curators of Library—Messrs. Lightbody, Garraway, Adam and M'Lachlan. Curators of Museum—Messrs. Glen, Wylie and Lyle. Officer—John Hamilton.

MEDICAL PROFESSION.—The physicians and surgeons of the city and county of Cork were called together by a requisition of the Western Medical Society, and held their meeting (the most numerous ever convened in the South of Ireland) at Lloyd's Hotel, a few days ago, to take into consideration the state of the profession in the south of Ireland, as well as the alterations contemplated by the Board of Superintendents of the County Grand Jury in the management of Dispensaries.

Dr. Beamish, of Bandon, was unanimously called to the chair. Dr. Jago, of Kinsale, was requested to act as secretary to the meeting. A variety of matter connected with the Profession was discussed, and much useful matter elicited, which will be laid before the Committee of the House of Commons. A committee was chosen to draw up a memorial to the Grand Jury on the proposed changes. The memorial was submitted to the general meeting the next day and adopted. They then proceeded to the election of a permanent medical committee, when the following gentlemen were elected, to whom the management of their interests was

confided, viz.:—Dr. Beamish, Bandon; Dr. Page, Kilworth; Dr. Nugent, Cork; Dr. Jago, Kinsale; Dr. William Murphy, Cork; Surgeon Fitzgibbon, Rosscarbery; Dr. Corbett, Innishannon; Dr. Bennett, Cork; Dr. M'Carthy, Bandon; and Surgeon Phelan, Clonmel. Dr. Bennett, of Cork, accepted the office of secretary to the committee. A deputation, consisting of the following physicians and surgeons, was appointed to present the memorial to the Grand Jury, and to confer with them on the proposed alterations, viz.:—Dr. O'Hea, Fermoy; Dr. Page, Kilworth; Dr. William Murphy, Cork; Surgeon Fitzgibbon, Rosscarbery; and Dr. Corbett, of Innishannon. We understand that the result of the interview between these gentlemen and the Grand Jury has been satisfactory, and has tended to remove the misapprehension of both parties.

The annual meeting of the Greenock Medical and Chirurgical Association took place yesterday, when the following gentlemen were elected office-bearers for the ensuing year:—Dr. Speirs, President; Dr. Mackie, Vice-President; Mr. Speirs, Treasurer; Mr. Auld, Secretary; Mr. Bruce, Librarian; Dr. Hill and Mr. Crawford (Gourrock), Censors; Dr. M'Donald, Superintendent of Museum.

WELLS.—A Medical Society has lately been formed in this city, to which Dr. Macmullen has been appointed President, and Mr. Bullen, Secretary and Treasurer; and on Friday the 27th ult, a meeting took place of many of its members, consisting of the most respectable practitioners in the neighbourhood, at the Swan Hotel, and formed the rules of the society; they afterwards sat down to an excellent dinner provided by Mr. Rolle in his accustomed style. On the cloth being removed, the usual toasts, "the King and Queen," were given. The President then proposed "Prosperity to the Wells Medical

Society," which was received with considerable applause. The President's health was next proposed and drank in the most flattering manner. In returning thanks, Dr. Macmullen introduced some appropriate remarks on the good effects likely to result from the establishment of such a society, and observed how gratifying it was to see gentlemen of a profession so respectable as that of medicine meet together in so friendly and cordial a manner as they did on that occasion; and in conclusion begged to propose the health of Mr. Bond. Mr. Bond returned thanks in an excellent speech, and observed it was his opinion that the Wells Medical Society would become an extensive and respectable one, and that he should always take a lively interest in its welfare. He then proposed the health of the secretary, Mr. Bullen. Mr. Bullen expressed his thanks for the compliment paid him, and hoped he should always discharge, to their satisfaction, his duties as secretary; he remarked on the central situation of Wells, with reference to the eastern part of the county, considering it a proper place of meeting for the members of the society; and alluded to the propriety of the profession observing and endeavouring to counteract any attempt at improper alterations in the medical institutions of the kingdom. The healths of Mr. Marshall and Mr. Gale were proposed, who, in returning thanks, severally expressed the interest with which they regarded the society. Many other appropriate toasts were proposed and drunk, and about half-past ten the President vacated the chair, and the members retired, highly delighted with the proceedings of the day.

EDINBURGH.—The Royal College of Surgeons being this day met, made choice of the following office-bearers for the ensuing year, viz.:—John Campbell, M.D., President; Thomas Lothian, Treasurer; James Keith, M.D., Librarian; William M'Gillivray, Conservator of Museums.

Examinators:—John Gairdner,

M.D., William Brown, David Clark, M.D., John M'Farlan, Alex. Macaulay, M.D., James Pitcairn, M.D., Richard Huie, M.D., James Begbie, M.D., James Scarth Combie, M.D., Archibald Inglis, M.D., Wm. Dumbreck, M.D., and James Simpson, M.D.

Extracted from the Records of the Royal College, by

WILLIAM SCOTT, *Secretary*.

PROFESSORSHIP OF CHEMISTRY.—MARISCHAL COLLEGE.—The examination for the Professorship of Marischal College, vacant by the death of Mr. French, commenced on Thursday last, in the presence of the Principal and Professors—the patrons of the office—assisted by Dr. Thomson, Professor of Chemistry in the University of Glasgow, and the Rev. Mr. Forsyth of Belhelvie—the two latter having been invited by the Senatus to assist in the examination. The candidates who appeared were—Dr. Henderson, Lecturer on Materia Medica to King's and Marischal Colleges, and Assistant to the late Dr. French; Dr. Laing, one of the Physicians to the Aberdeen Infirmary; and Dr. Thomas Clark of Glasgow.

A difficulty having arisen as to the interpretation of the clause in the Deed of Foundation, which requires that the candidates shall have received a regular academical education, the Senatus divided upon the point as to whether Dr. Clark, by producing a diploma of M.D. from the University of Glasgow, had complied with the above requirement of the founder, and was therefore eligible for admission as a candidate. The question having come to a vote, there appeared

<i>For admission.</i>	<i>For non-admission.</i>
Principal Dewar,	Dr. Glennie,
Dr. Skene,	Dr. Knight,
Dr. Davidson,	Professor Brown,
Professor Cruikshank.	Dr. Black.

By this equality of votes, the question came to be decided by the casting vote of the Principal, who gave it in favour of admitting Dr. Clarke as a

candidate. Upon this, certain of the Professors, who had voted for non-admission, entered their dissent and protest upon the record.

The examination of the candidates was then proceeded in, and is still going on. It is, however, expected that it will be concluded to-day, after which the Examinators will report their opinion to the Senatus, who will then proceed in the usual form to elect the Professor.

APOTHECARIES' HALL.

NAMES of gentlemen to whom the Court of Examiners granted Certificates of Qualification on Thursday, October 10th.

Richard Allen	. Leicester.
Henry Barrett	. Kingston, Berks.
John Bennett	. Manchester.
Francis A. B. Bonny	. Brentford.
Robert Crisp	. Peterborough.
Henry Acheson Crozier	. Totness, Devon.
Frederick Davenport	. Egham, Surrey.
Edward William Eton	. Bedworth, Warwicks.
William Jenkin	. Cornwall.
Thomas Lloyd	. London.
John Warburton Moseley	. Burslem, Staffordsh.
David Morgan	. Llandilo.
Thomas Howel Stevens	. Barnstaple.
William Saul	. Green Row, Cum-berland.
Wm. Stanhope Taylor	.
Jonathan Gawtress Wade	. Wath, near. Rother-ham.
Francis Welsh	. Taunton.

BOOKS.

A Concise Treatise on Dislocations and Fractures, being a Selection from the Best Works, Illustrated by Fourteen Plates. New Edition, 12mo. London, 1833. Renshaw and Rush.

We strongly recommend this little work to every one engaged in the practice of surgery. It is a multum in parvo.

The Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery and the Diseases of Women and Children, illustrated by numerous Plates. By DAVID D. DAVIS, M.R.S.L., Professor of Midwifery in the University of London. Part XXIV. London 1833. John Taylor.

An Inquiry into the Disease called Cholera Morbus, showing its Nature and suggesting the Means of Cure. London 1833.

Thoughts, on Medical Reform by a Retired Practitioner. London, 1833. B. Fellowes.

A New Method of Making Anatomical Preparations, particularly those relative to the Nervous System. By JOSEPH SWAN. Third Edition, enlarged. 8vo. Part III. London, 1833. Longman and Co.

Surgical Essays, the result of Clinical Observations made at Guy's Hospital. By B. B. COOPER, F.R.S., Surgeon to Guy's Hospital, Lecturer on Anatomy, &c. &c. Royal 8vo. Pp. 281. Four coloured Plates. Lond. 1833. Longman and Co.

This work closely resembles the Essay of Sir Astley Cooper and Mr. Travers, and is replete with much surgical information.

Observations on Obstetric Auscultation, with an Analysis of the Evidences of Pregnancy, and an Inquiry into the Proofs of the Life and Death of the Fœtus in Utero. By E. KENNEDY, M.D. Pp. 288. Dublin, 1833. Hodges and Smith.

Lunacy versus Liberty. A Letter to the Lord Chancellor. By WILLIAM GRIGGS.

A Series of Anatomical Plates, in Lithography, with References and Physiological Comments in illustration of the Structure of different parts of the Human Body. By JONES QUAIN, M.D. Fasciculus I. Division I. Muscles. John Taylor.

The Sanctum.

Advertisement Extraordinary.—A respectable metropolitan lecturer near the West-end, being anxious that his ensuing course should be reported for insertion in a contemporary, wishes to meet with a gentleman properly qualified to do the same. No one need apply who does not possess a thorough knowledge of *blarney*, and is not able to report such words as *post hoc* and *propter hoc* in the twinkling of a gallipot. No one who has been a reporter before, or who understands Latin well need apply. Letters will be received (post-paid) and personal references attended to any hour after dark, by Dr. —, — street, — square.

Magnetism.—A tom cat, a great friend of ours, was lately cured of a severe tic-douloureux of the stomach, by having a magnet passed over a piece of cheese before he (the dear fellow) took it for his supper.

Important Clinical Lecture.—A clinical lecturer, not many hundred miles from Hyde Park Corner, in describing a case to his pupils began, by saying that the patient had died, but he really did not know why; she was not left to die, neither had she any right to die. However, on examining her body, he found, to his surprise, that "the blood was everywhere

but where it should be;" now this he thought formed a very strange symptom in the case, and it was not right that the process of sanguification, or as he termed it, the "business of blood-making," should be left to go on in such a strange way, and ultimately kill the patient without his noticing it to his pupils. He next went on to describe a case of "splitting headach," in doing which he fairly "split the ears of the groundlings;" the word "splitting" in his ears sounded more medical than any double Dutch or dog Latin expressive of the same term could do. In fact, the lecturer and his lecture were as oddly assorted a couple as could be well met with in any hospital walk in London.

Our correspondent who dates from the Spooney Flats, Connecticut county, shall be immortalised in the next Sanctum.

Pauper Physicians and Surgeons.—A correspondent on whose veracity we can rely, informs us that there are at least three hundred professional men on the pauper lists of the metropolis.

Intercepted Letters.—We have received numbers of these lately, and if the parties for whom they are intended do not call for them before the publication of the next Sanctum, they will be treated *selon les règles*.

A very funny M.D.—A respectable physician whose lectures have gained him great notoriety, is noticed in a contemporary as remarkable for interlarding puns and smart sayings with his medical axioms. Rather a novel qualification this!

Important Intelligence.—Our correspondent, W. C., who wishes us to communicate what he considers important intelligence to our correspondents and readers is informed that we shall willingly do so when we have the opportunity. He is not, perhaps aware of the difficulty that exists in procuring it correct. We are obliged to him for his kind letter.

Mr. Griggs.—Reader, the worthy gentleman whose name you have just read is a member of the baking profession, and resides in the Edgeware Road. He has had the misfortune to be confined in Mr. Finch's Lunatic Asylum, where he considers he has been most unjustly and unkindly treated; and having got out, has determined on writing a book, which he has sent us to notice, but which we shall not do except specially requested by our readers, until when, most immortal Griggs, farewell!

We have received a letter from VERAX, and a communication from the Editors of the *Journal des Connaissances Medico-Chirurgicales*, which shall be attended to.

ALL Communications and Books for Review to be forwarded (free of expense) to the Publishers, 356, Strand, near King's College.

THE

London Medical and Surgical Journal.

No. 91.

SATURDAY, OCTOBER 26, 1833.

Vol. IV.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE IX., DELIVERED FEB. 28, 1833.

GENTLEMEN,—Towards the conclusion of the last lecture I was noticing the treatment of that form of periostitis which sometimes arises during a mercurial course, employed for the cure of syphilis, though chiefly in persons who are not careful of themselves while subjected to the influence of this mineral, either committing excesses in diet, or exposing themselves to damp and cold. It might, perhaps, here be more correct to say, that these circumstances in venereal patients tend to prevent the salutary influence of mercury on syphilis, and to bring the system into a condition, in which periostitis is readily excited. There may also be particular states of the constitution, independent of such causes, creating a predisposition to inflammation of the periosteum, which is then excited by the further derangement of the health, produced by the united effects of the venereal disease and mercury together. Different opinions are entertained by surgeons respecting the right mode of treatment in this form of periostitis. Many practitioners deem the antiphlogistic plan, combined with the continuance of mercury, the most advisable practice, and, not only in this instance, but in all forms of periostitis, whether depending on syphilis or not. But in those cases which have been produced by the injudicious and negligent use of mercury, I believe it is a better plan to discontinue that medicine, at least for a time, that is to say, until the derangement of the health has had a little while to subside: afterwards you may resume mercury, if necessary, under more advantageous circumstances. You will meet with many cases, however, which cannot be relieved by mercurial treatment; and certainly it is

improper to push mercury while the constitution is deranged by the combination of circumstances I have mentioned, namely, by the inattention of the individual to take proper care of himself while taking the medicine, and by the influence of the original disease on the periosteum in the peculiar state of the constitution thus induced. Under such circumstances, the mercury should be discontinued, at all events, for a certain time, and, after having had recourse to leeches and purgatives, you may give light tonic alteratives, especially sarsaparilla, with small doses of the compound powder of ipecacuanha, James's powder, or hyoscyamus, or opium, if the pain be very severe. When the constitution has improved, if the periostitis require it, mercury is now to be given, and you may even push it to some extent, cautioning the patient, however, against imprudently exposing himself to cold, living too freely, and following his usual exercises in the open air. You will generally find, that when the periosteum inflames during the mercurial treatment of syphilis, and the patient's constitution has not something wrong about it, independent of the causes here considered, the disease is brought on in the manner I have mentioned. Cases are frequently met with, in which colchicum is found to give considerable relief; and there can be no doubt, I believe, that one form of periostitis occurs chiefly in rheumatic constitutions, and that, in them, it is often excited by the disturbance of the health, occasioned by the united effects of mercury and syphilis together. When periostitis gets into the chronic stage, frictions with iodine liniments, or even blisters, are exceedingly useful; but in the acute stage, leeches, fomentations, and poultices, or the soap plaster with belladonna, are the right applications. When I come to the venereal disease, the subject of *nodes* will bring us into close contact with this disease again; I shall now pass on to the consideration of

Inflammation of bone.—This may be either acute or chronic, simple or specific, just like inflammation of the soft parts. In the chronic form of the disease, a slow enlargement of the bone is produced, attended with a degree of hardness perfectly incompressible. In no

VOL. IV.

C C

species of inflammation of the osseous texture, does the swelling come on so rapidly as that of the soft parts. It requires a longer time for its production; and, in the commencement of the affection, considerable pain always precedes the swelling. Then I have to notice, that the latter effect, slow as it is in its occurrence, is still slower in disappearing. In certain instances, chronic inflammation of a bone will follow a blow, or some other form of external injury, and then the pain is not always particularly severe, nor is it constantly accompanied by any material constitutional disturbance; but when the inflammation has arisen as a consequence of syphilis, or of the abuse of mercury, in peculiar and unfavourable conditions of the health, then the pain in the part is generally considerable, and remarkable for its periodical exacerbations, which usually come on in the night-time.

In *chronic inflammation of a bone*, gentlemen, the part is generally enlarged by an increased deposition of phosphate of lime within its texture, in consequence of which it acquires greater density, solidity, and weight. In the venereal inflammation of bones, when there is enlargement produced, you will generally find that the bone is heavier than natural, as you see in this example. You may observe, that it is not only increased in size but in weight, which changes depend upon the increased quantity of phosphate of lime that has been deposited in its texture. However, in some other kinds of inflammation of bones, there is no increased deposition of lime in the osseous texture, and consequently their weight is not augmented. Sometimes, instead of rendering a bone heavier than natural, inflammation will have the directly contrary effect, rendering the part lighter and more porous than common. This tibia, which has indubitable marks of having suffered from inflammation, is lighter than natural; and you will observe, that the vertebrae, which I now show you, are surprisingly light: this sacrum has not one half of the weight which it would have had in a healthy condition. But, gentlemen, I should mention, that, though in our Museum catalogue these latter specimens are entered as instances of the effects of inflammation on bones, the history of some of the cases is not known; therefore, doubts may exist about the causes which produced so extraordinary a lightness of the osseous texture, and whether it has been truly brought on by inflammation. But there are other specimens in the Museum, in which we know very well, from the history of the cases, that the increased porosity of the osseous texture, and the diminution in its weight, were produced by the effect of inflammation. Here is an example of what I am referring to: it comprises the sections of a femur, which has been fractured, a good deal of inflammation has followed the injury, and its ends are manifestly more porous than the rest of the bone, and their solidity diminished. Indeed, you will generally find in frac-

tures, and more especially in compound fractures, that the ends of bones become porous and light in consequence of the inflammation which ensues.

Then, gentlemen, I need hardly tell you, that inflammation renders the surfaces of bones particularly rough, changes their figure, and produces an altered appearance of their prominences and edges. Here are specimens of the roughness, protuberances, and other changes, produced on the surfaces of bones, by inflammation of the osseous texture.

In scrofulous inflammation of a bone, you will frequently find, that the part becomes lighter than natural, and that in its interior a soft greasy kind of substance is deposited, at the same time that more or less of the phosphate of lime is deficient. Small cells are formed within the osseous texture, in which the soft greasy substance, which I have mentioned, is deposited, the earthy matter being absorbed in proportion. While these changes are going on in the interior of the bone, you will frequently find a considerable quantity of bony matter thrown out on its external surface, and forming osseous irregularities, which sometimes surround the whole head of the bone, and shoot out like sharp spiculae from it. You will find that scrofula is always most disposed to attack the heads of bones, and other parts of the skeleton, whose texture is spongy.

In the disease called *white swelling*, you will notice, that the bone is softened; that there is an undue absorption of the phosphate of lime from it; and that a deposition of a caseous greasy substance takes its place. In this disease, you will also observe the spiculae, or irregularities of bone, which sometimes reach, in the manner I have described, a considerable distance from the surface of the bone. I will show you various specimens of the effects of scrofulous inflammation of the bones, when the *diseases of joints* will come particularly under our consideration.

Inflammation of bone, kept up for some time by the pressure of the head of another bone, thrown out of its natural situation, sometimes leads to a very curious change in the bone thus pressed upon, as well as on the displaced head; a kind of *ivory deposit* may be secreted on the surface. You may observe a deposition of this kind on the head of the bone, which I now show you; it certainly appears very much like ivory, and seems to be produced as a substitute for cartilage, and to be capable of bearing a degree of friction without becoming inflamed, or an ankylosis, or complete growth of the two other bones to each other being the result. It is sometimes termed the *porcelain deposit*.

Sometimes inflammation of a bone leads to ulceration of that texture, or to what surgeons term *caries*; for, though this process corresponds in all essential points to the ulceration of the soft parts, yet it is customary not to call it ulceration, but to apply to it the other

name, which has been specified. A very good example of caries is seen in this radius, on which the ravages of a process analogous to ulceration, have occasioned almost a destruction of the part. I have already shown you different specimens of simple absorption of the bony texture, caused by the pressure of neighbouring tumours. A good illustration of this sort of change is now before you:—the greater part of this thigh-bone has been absorbed, in consequence of the pressure of a tumour on the thigh. Now, the simple absorption of bones differs essentially from caries, with which there is always a secretion of pus; whereas a mere removal of the osseous texture, produced by pressure, is not accompanied by any secretion of purulent matter, as is illustrated in the remains of the thigh-bone you are now examining; and, in aneurisms within the chest and abdomen, by the pressure of which diseases, the vertebræ, ribs, or sternum, become in numerous instances extensively absorbed; yet there is, as I have said, no secretion of pus; the osseous texture is quietly taken away, without the formation of any abscess. Thus, gentlemen, you see, that a good deal of difference exists between caries and simple absorption of bone.

Then, gentlemen, while simple enlargement of bones, attended either by an increase, or a diminution in their weight, is frequently the result of chronic inflammation of their texture, you will often find *suppuration in the cancellous structure* of bones, and *necrosis*, or the death of the harder parts of the osseous texture, are common consequences of acute inflammation of bones, that has gone beyond a certain pitch. Bones will not bear a violent attack of inflammation without a portion of their structure being likely to perish, and then the disease receives, as I have explained, the name of *necrosis*. In certain instances, suppuration takes place in the medullary texture; and this sometimes as a consequence of deep-seated chronic inflammation within the cancelli, or cavity of the bone. An interesting case was lately recorded in the *Medico-Chirurgical Transactions* by Mr. Brodie. A patient had been labouring under a considerable swelling at the lower part of the tibia for eighteen years, without being able to procure relief from any kind of treatment that could be thought of. Mr. Brodie determined to perforate the bone, conceiving that matter might be confined within it. The trephine was applied, and a small abscess found in the cancellous texture of the tibia. So small was this abscess, that it contained only about two drachms of pus; yet it had kept up a continual state of suffering for the extraordinary length of time which I have mentioned. You will also find in Hey's *Practical Observations on Surgery* other cases of a somewhat similar description.

A bone, that has been enlarged by inflammation, is not so quick in returning to its original size as the soft parts, when they have

been swelled from a similar cause. In fact, when a bone has once undergone an increase of size at any part of it, a considerable time generally elapses before it recovers its natural dimensions; and sometimes it never does so, but remains ever afterwards more or less altered in its shape and diameter; and this, notwithstanding all morbid action may have ceased within it. It is only the spongy parts of a bone which suppurate: at all events, if suppuration ever takes place in the harder parts of bones, there must have been some previous disease in them, the effect of which has been that of diminishing their solidity; for you will occasionally find that the harder parts of bones will lose their consistence and solidity, and in this case they may have matter formed within them. Suppuration, then, takes place chiefly in the cancellous structure, and in the heads of bones. We occasionally meet with instances of it in the diploe of the cranium. Generally, when suppuration takes place in a bone, in proportion as purulent matter is secreted, the earthy parts of the osseous texture become absorbed, and thus a considerable cavity may be produced. After the pus has collected in the cancellous structure of bones, it usually makes its way after a time through their walls, and, gradually making its way to the surface, collects under the skin. On the bursting or puncture of the abscess, the pus escapes, and the patient receives considerable relief. Such disease used formerly to be known by the name of *spina ventosa*: perhaps, the two cases, related by Mr. Brodie, would have been considered as examples of *spina ventosa*, though, from some causes, which are beyond our comprehension, the matter remained pent up in the interior of the bones for an immense length of time. Where the suppuration is accompanied by much injury of the medullary membrane, the case will be combined with necrosis.

Most of these preparations before me illustrate the roughness of the surface, and the change of shape and size, which we commonly meet with in carious bones; for this disease often follows an inflammation of the osseous texture, and more especially some forms of it, proceeding from specific or constitutional disorders. When exostoses have acquired considerable size, they are frequently attacked by caries or necrosis: the new bony formation seems to be even less capable of bearing inflammation, than the original part of the bone.

Acute inflammation of a bone is to be treated in the same way as idiopathic periostitis, that is to say, with leeches, cold applications, or poultices, saline aperients, and perfect quietude of the part. Sometimes you may also take away blood from the part by cupping. Cases occur, in which you find warm applications afford greater relief than cold ones, and then I advise you always to consult the patient's feelings, and if he express

a preference to warm applications, I should never hesitate about the expediency of employing them. In chronic inflammation of bone, the treatment should be regulated by the consideration of the causes of the disorder; you should endeavour to ascertain whether it is connected with syphilis, scrofula, or that peculiar state of the constitution which is brought on by the combined effects of syphilis and an improperly conducted mercurial course. As far as my own experience enables me to judge, I think you will rarely meet with inflammation of the bones in venereal patients, unless they have been employing mercury, and I believe not often then, unless they have been exposing themselves to the imprudences I have mentioned, while taking that medicine, or are individuals whose constitutions are originally bad. You will never be able to say positively, whether chronic inflammation of a bone is venereal, or not, by the mere appearance of the part; you must join with your reflections on the state of the part itself the history of the case. You must study attentively the character of all the other symptoms which the patient either has had, or has at the present time, and it is only in this manner, that you can arrive at a just conclusion. Then, if the affection of the bone be dependent on the venereal disease, you should prescribe mercurial treatment, for without this medicine you would have great difficulty in entirely relieving the patient's sufferings, and diminishing the enlargement. Perhaps this form of syphilis is not so readily cured by common medicines, as the other forms of that disease; for we know, that the ordinary forms of syphilis may all be cured without mercury, although that medicine is usually preferred, on account of the greater certainty with which it prevents the occurrence of secondary symptoms; but nodes and the chronic inflammation of bones from syphilis often make extraordinary resistance to the power of every medicine but mercury. But, in such cases, there is a period beyond which mercury ought not to be given, and if you were to continue its use till all the effects of inflammation had been totally removed, and the swelling quite dispersed, you might kill your patient sooner than accomplish your intention. Hence, when you have every reason to believe, that mercury has suspended the specific morbid action; when you find, that the pain has subsided, that the patient is able to rest better at night, and that other favourable symptoms announce an amelioration in the state of his constitutional health, then you may safely relinquish mercury, and commence with the compound decoction of sarsaparilla, as an alternative well calculated to complete the cure. If this fail, try other light tonics, with antimonials, or Dover's powder. In order to reduce still more the swelling, you may have recourse to blisters, or the ointment of the hydriodate of potash, and other iodine applications, but do not think of salivating your patient until the node entirely disappears.

The next affection of the bones, gentlemen, on which I wish to deliver a few remarks, is *caries*. Some years ago, *caries* and *necrosis* were confounded together; therefore, when you read books, published thirty or forty years ago, you will generally find, that the two diseases are not properly discriminated from one another, though nothing can be more certain than that caries is as different from necrosis, as ulceration of the soft parts is from mortification. While caries is one of the consequences of inflammation, or an irritated state of bone, some of the texture of which is absorbed without its vitality being destroyed, necrosis involves the complete destruction of the bone, or of a part of it. In necrosis, vast efforts are generally made by nature for the reparation of the portion destroyed, and frequently the whole shaft of a bone is reproduced, but caries is not usually followed by any thing in the shape of repair at all comparable to this. The points, in which caries resembles ulceration, are the following: caries and ulceration are each preceded by inflammation, each is attended with the formation of purulent matter, each may be followed by the production of granulations, and each may depend either on a local or a constitutional cause. Sometimes caries and necrosis are combined together; frequently when there is caries, dead fragments of bone are found in the cavity formed by that process, and this happens especially in caries of the vertebrae. When a considerable portion of their substance has been removed, pieces of dead bone are frequently found in the midst of the carious parts. We see an analogous circumstance in ulceration, which is often combined with sloughing. It seems, that, during the progress of ulceration, portions of the substance of the part perish, and are detached, and then remain in the cavity formed by the ulceration. The venereal inflammation of a bone sometimes produces caries, and sometimes necrosis, and not unfrequently both together. I have already explained to you, that simple absorption of a bone, as illustrated in cases where it has arisen from the pressure of aneurismal and other tumours, is quite a different affection from caries.

The bones are all liable to caries; but you find that it is the spongy parts of bones, the heads of bones, and the spongy bones themselves, which more frequently suffer from this disease, than the solid, compact, firm parts of them. Thus you meet with caries oftener in the head of the tibia, in the vertebrae, in the sternum, in the upper head of the femur, or in its condyles than in the generality of other parts of the skeleton.

Sometimes we can trace the effects of caries to a local cause, such as a blow, or other form of external violence; in particular, severe gunshot wounds, which happen to injure the bone. But I should state, that caries is more frequently the result of a general disease of the system, and more especially of two diseases, namely, scrofula and syphilis, particularly the

first. In whatever manner the disease may be produced, there is always, in the early stage, a degree of pain and swelling in the neighbouring soft parts; inflammation arises, an abscess then follows, and it bursts, and discharges a thin ichorous matter, which has a peculiarly offensive smell, and turns a silver probe black, from its containing sulphureted hydrogen gas. After the abscess has burst, it does not heal, but pale fungous granulations are generally thrown out, which bleed profusely on being touched with a probe; indeed, this ready disposition to bleed is one of the common symptoms which will lead you to suspect, that the bone under the sore is not sound. You will observe, that the ill-conditioned granulations about a fistulous opening, leading to a carious bone, have a remarkable propensity to bleed on being slightly touched. Sometimes when the disease is in the head of a bone, and you introduce a probe, you will not merely touch the bone, but the instrument will pass still more deeply into the cancellous structure, without any resistance from the osseous texture. This is sometimes exemplified in the bones of scrofulous joints. You will, also, sometimes find, that small portions of bone are discharged from the fistulous opening, and minute fragments detached from the carious surface.

Generally, if we except the circumstances, that caries is analogous to ulceration, and that it depends sometimes on local and sometimes on constitutional causes, we remain ignorant of various particulars respecting it. Perhaps, if the nature of a bone, the characters of its texture, and organisation, its dull innervation, and deep concealed situation, would allow a skilful pathologist to trace the commencement and progress of caries more easily, he might detect several varieties of the disease, and succeed in pointing out their peculiarities. But such an investigation cannot be so successfully made as in the soft parts. Much yet remains to be made out respecting the nature of caries, no pathologist has hitherto been able to define some of the differences which exist in the varieties of this disease. We know that some kinds of caries are curable by means different from those which are proper for other forms of it; and also that caries is sometimes a symptom of one disease and sometimes of another; yet we cannot always point out the minute differences in the appearance of the several cases. The *worm-eaten* caries is one peculiar variety of it, different from all others; I believe there are some specimens of it in the museum, and they shall be shown to you at the next lecture. In the *worm-eaten* variety of the disease, the bone is perforated at innumerable points and in various directions, and its difference from common caries is immediately apparent; for the latter merely produces a chasm the surface of which is marked by irregularities; but the *worm-eaten* caries presents appearances exactly similar to those which would be caused by the

kind of destruction to which the epithet refers. Around scrofulous caries, you will frequently observe a deposition of new bone in the form of spiculæ, inequalities, and protuberant masses. No doubt, in many instances, where the bone is inflamed, the periosteum partakes in the affection, and is materially concerned in producing the changes which take place; or, at all events, the vessels of the periosteum, for the periosteum itself is merely a medium for the transmission of vessels into the texture of the bone. The vessels, then, of the periosteum must be considered as frequently acting a conspicuous part in the diseases of bones, and in their reparation.

The treatment of caries, gentlemen, must be regulated by the views entertained of its cause. If it arise from a local cause, that is, from local inflammation originating, from and following, external violence, of course, as you could not suspect the constitution of being concerned in bringing on the disease, the treatment should be restricted principally to local means. In other instances, where you have reason to believe that the patient is scrofulous, or has syphilis about him, then the treatment ought to comprise internal remedies calculated to rectify and amend the constitution generally. But, even when you have reason to think that the constitution is concerned in the production of the disease, it will be necessary to diminish the surrounding inflammation; for, it is found in caries, that a greater activity prevails in the circulation around the part. Hence, if the part be injected after death, you will see a greater vascularity in it than natural. There is in fact increased action about caries as there is about ulceration; and, viewing the case in this light, it will be evident, that antiphlogistic plans are proper in the first instance. Afterwards it will be your aim, either to remove the carious part of the bone, or to produce such a change in the action of the vessels of the part, as shall cause a cessation of the carious affection. With respect to the removal of the carious portion of bone, there are some who think that more can be done with a cutting instrument in one minute, than can be accomplished by other means in many months. And no doubt when the part can be scraped or cut away with sufficient facility, the practice is sometimes right, as the cure will take place more rapidly. Yet, there are cases in which the disease may be stopped by the use of medicines; thus when caries is dependent on syphilis, mercury will sometimes bring about a cure; and, though scrofula is less under the controul of medicine, yet, if we support the constitution by proper means, nature will occasionally bring even scrofulous caries to a favourable termination. Notwithstanding what is sometimes alleged, I believe, that caries from scrofula often ends in ankylosis, and that such a mode of cure is not only very possible, but absolutely a thing of daily occurrence. I am surprised that such a circumstance should have been doubted, when we

recollect that scrofulous disease of the vertebrae, when cured, is only cured by the establishment of anchylosis. When you find that you can safely cut away the carious portion of a bone, and that you are not likely to bring about a cure by other means, I can see no objection to the practice. Some other means may be useful, as for example, counter-irritation, which acts by arresting the morbid action going on in the carious part of the bone. The disease has also been sometimes benefited by the application of nitric acid and lunar caustic; these act on the same principle as counter-irritation, namely, by stopping the morbid action in the diseased part. With the same view, the actual cautery is commonly used in France, where surgeons as familiarly use the actual cautery, as we do the nitrate of silver, or caustic potash. The cautery destroys the carious part—causes, in truth, a necrosis—exfoliation follows—in other words, the dead piece of bone becomes loose, it is thrown off, and the surgeon takes it away, and the ulcer heals.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

*At the Meath Hospital, or County of Dublin
Infirmary, Session 1832-33.*

LECTURE XV.

Fever, and the Theory of Broussais.

GENTLEMEN,—At our last meeting I mentioned that it was my intention to devote the remaining lectures of our present course to the consideration of fever; I now proceed to the examination of one of the most important and difficult topics in the whole range of medical science. It is rather a remarkable circumstance, that we have not had, since I took charge of the wards, a single case of what could be called pure fever. In every case which came under our notice, there were, in addition to the fever, unequivocal evidences of visceral inflammation, more or less intense; and, accordingly, as you pursue your studies in pathology, you will be convinced, by repeated experience, that this holds good in more cases than you were previously led to imagine. Hitherto, the clinical lectures which I have delivered in this theatre have been devoted to the consideration of isolated cases of disease.

We have not as yet touched on the subject of fever; but now, after you have seen cases of most of the visceral inflammations, you will come to the examination of fever with greater advantages. The ordinary mode of lecturing on the practice of medicine in these countries is, to commence with the subject of fever, for no reason that I can understand, except that it holds the first place in the nosology of Cullen. I have always pursued a different course, for the following reasons.

If we compare the state of our knowledge

of fever now with what it was in former times, we shall see that all our improvements spring from a single source, and that is, our knowledge, *not of the essence of fever—not of the laws which govern epidemics—not of the remote causes—not of the phenomena of crisis, but of the number, extent, nature, and effects of the local inflammations which may precede, accompany, occur in the course of, and complicate, the disease.* It is to this knowledge we have really advanced; and to attempt the study of fever without possessing a thorough acquaintance with the nature of local inflammations is totally absurd. How are we to understand the nature and symptoms of a nervous fever without a knowledge of the various shades of cerebral irritation, or a catarrhal fever, without an intimate acquaintance with the varieties of bronchitis, pneumonia, and congestion of the lungs? How can we investigate the phenomena of a gastric and bilious fever without a knowledge of that most Protean of diseases, gastro-enteritis?

It may be said, there are simple fevers without any of these local inflammations. True; but they are *very rare*; and it must always be remembered, that in fever, our incapability of discovering any symptoms of a visceral lesion does not imply its non-existence. How often has the fact been established, that many fevers, supposed to be simple, have been in reality complicated with latent local disease. *Essential fevers*, by which is meant fevers without any local inflammation, were at one time looked upon as diseases of frequent occurrence; they are now considered to be among the "*cas rares*." To this point I shall again return, and for the present merely remark, that all the well-marked local symptoms, in a case of supposed essential fever, are the result of visceral diseases more or less developed. Thus, the vomiting and the hiccup, which the essentialists place to the account of debility, or some other equally unmeaning term, are to the pathologist almost always the signs of a gastritis,—the diarrhoea and tympanitis of gastro-enteric inflammation. Again; that most abused of terms, *effusion into the chest*, by which so many die, is to the essentialist the result of debility; but the true pathologist shows, that in nine cases out of ten, it proceeds from an unsuspected and neglected bronchitis or pneumonia. Do not the delirium, the convulsions, and the coma, point out, most commonly, an excited state of the brain? Will not the pathologist, by investigating disease in this way, be likely to obtain what the essentialist never could arrive at—a rational key to treatment? He is not at one time prescribing for debility without knowing the cause, or for putrescence, or for acidity, or alkalinity of humours, but he is attempting to remove or modify a gastritis, a pulmonary or cerebral inflammation, or congestion.

Gentlemen, we owe a great deal of the improvement we have made in our knowledge of fever to M. Broussais, one of the most

remarkable men of modern times. Of him it may be justly said, that there are few men who have been more lavishly praised and more blindly followed; few who have been more misunderstood, both as to the nature and extent of their labours; and few, indeed, who more strikingly exhibit the shock which may be given to their own reputation, and the injury which may be done to science, by rashly overstepping the bounds of strict and careful induction. I am anxious, for many reasons, that you should acquire clear notions on the subject of the theory of Broussais before we part, because, in the first place, after having examined it we shall be better able to ascertain the actual state of the science with respect to fever, and, in the next, because a great deal of misapprehension prevails on the subject—the result of national prejudice. If medical men, and particularly medical teachers, were to learn before they attempted to describe, and to understand before they dared to anatomise, it would tend much to exalt the dignity and importance of our profession. But, unfortunately, it is much easier to abuse than to investigate; it is much more congenial to some minds to endeavour to debase others to their own level, than to exalt themselves by a noble rivalry in contributing to the treasures of science.

I wish also to bring this matter before you, because we have been accused of Broussaisism in this Hospital by some persons who seem not to understand what the doctrines of Broussais are. But I deny the charge of being a blind follower of any theorist in medicine, and particularly of M. Broussais. I can safely appeal to the successive classes which have attended this hospital, whether I have not, when drawing their attention to the merits, always pointed out the errors of Broussais, and particularly, whether I have not always contended against his theory of fever, to which the downfall of his reputation is mainly attributable. Because, as the progress of science disproved the theory, the facts on which not only it but all his other conclusions rested, though well established, were in their turn doubted or disbelieved. Yet, putting aside his theory of fever, it must be acknowledged, that there is scarcely a part of practical medicine to which M. Broussais has not made the most valuable additions. Nothing can exceed the ignorance of the real nature of the doctrines and extent of the writings of Broussais, except the virulence with which every puny pretender in medicine attacks them; at the same time ignorant of this, and, generally speaking, of all other medical doctrines. Ask any of these gentlemen what the doctrines of Broussais are, and the answer is, that "*fever is nothing but gastro-enteritis; that all diseases proceed from gastro-enteritis; and that to cure all diseases we must put leeches on the abdomen.*"

Such is the idea which I have found to prevail generally, and yet nothing is more

erroneous. In the first place, the doctrine of Broussais is, that fever may result from the irritation of *any* organ which is sufficiently powerful to be transmitted to the heart. (See his 111th proposition.) "*Intense irritations of all organs are transmissible to the heart. Then its contractions are rapid, the circulation is accelerated, and the increased heat of the skin causes a painful sensation. This is what we call fever, which is here considered in a general and abstract sense.*" In the next place, he never said that all diseases proceed from a gastro-enteritis, as one of the fundamental principles of his doctrine is, that disease of *any one organ of importance may induce disease in any other organ by sympathetic irritation, transmitted either through the systems of organic or animal life.* Lastly, with respect to treatment, I need only refer to his therapeutics to prove the falsity of the statement that he attempts to cure all diseases by leeching the abdomen. On the contrary, no one can more strongly inculcate the value of local depletion in affections of the head, chest, or any other part when necessary. This is, I think, sufficient to overturn the false notions which exist on the subject of Broussais's theory.

The doctrine of Broussais has received from himself the imposing name of the *physiological doctrine*, as distinguished from all preceding ones. Objections have been raised to this denomination by many persons, but in my opinion needlessly; for if a doctrine be true, it must be physiological; and all we have to do is to examine whether the doctrine of Broussais really deserves so proud a name. But what does he mean by calling it the physiological doctrine?—Simply this, that, according to these views, disease is not to be considered as a *new* condition of the economy, but as resulting from a plus or minus degree of organic vitality. In this way he groups all diseases under a common formula; they are the result not of any new accidental freak of nature, but proceed from causes and operations already familiar to her. For example, the vascularity of the stomach during digestion is a physiological condition; but when a little more increased, it is a pathological state, constituting *gastritis*. The difference is merely in degree. Thus he gets rid of what he denominates "*entities*," by which is meant separate unanalogous states of the economy, and of course attacks the mode of treatment by specifics, which at first he denounced altogether, but has since been forced to admit to a certain degree. In his subsequent explanation of the action of bark in fever, he exhibits a sad instance of striving against truth, and of having recourse to sophistry to make facts square with theory. Let us, however, do him justice. There can be no doubt that too much faith was put in specificism; and the doctrines of Broussais have contributed greatly to shake the specific treatment by drawing the attention of practitioners to the similarity in

essence of most diseases. For instance, a patient has delirium proceeding from an irritation of the brain; this ceases, and the stomach becomes affected, and he gets an attack of vomiting. Now the delirium in the first instance, and the vomiting in the second, are results of the same morbid state; and the diseases only differ by their situation, the principles of treatment are precisely the same.

We come now, gentlemen, to one of the most striking parts of the doctrine of Broussais; a part in my mind the most objectionable, and yet the least objected to, particularly in these countries, because the objectors to Broussais are but little acquainted with his works. To the true Broussaisist there is no such thing as specific inflammation; all organic diseases are either diseases of inflammation, or of ab-inflammation; that is, they consist either in a plus or minus state of local vitality. Were this true, how beautifully simple would the practice of medicine be! In fact, the first announcement of this doctrine drew crowds of admiring disciples, who were captivated by the wonderful reduction of chaos into order, which seemed to be effected by the mighty genius of a single man.

In its searches after truth, the human mind longs for a principle and is allured by a specious generalisation. So it was with the followers of Broussais. They were delighted with the simplicity of the new doctrine, and saw in it a complete removal of all the difficulties which embarrass the pursuit of practical medicine. But if they reflected calmly they would find that in considering diseased action there are characters discovered which are not reducible to difference of situation, and which cannot be explained by the closest anatomical examination. There is something more to be taken into account than the difference of organic vitality as far as degree is concerned. There is a difference, inappreciable by the senses, which makes one sore yield to a peculiar medication and another to another. In a scrofulous or syphilitic ulceration there is inflammation without doubt, but it is not ordinary inflammation, *because it does not yield to ordinary means*, and it is to this difference it owes its specific character. How did Broussais get over this? By denying the existence of such diseases as scrofula and syphilis as distinct affections, a proceeding which drew down the reprehension of every thinking and practical man, and led many to doubt all the other statements of an author who could be guilty of such a medical error. If there be no specific inflammations why does the contagion of measles produce measles, or why does the contagion of syphilis give rise to syphilis? If in the latter disease there be nothing but irritation and inflammation, why does it not in all cases yield to ordinary antiphlogistic treatment? Broussais attempts to explain the cure by mercury by supposing a revulsion of irritation from the affected parts to the viscera. Admitting this, why is it that mercury is the best revulsive in

syphilis? The specific character of the disease appears under this view of the subject as well as under any other. It may be granted that the term, *specific*, is objectionable. But can we do without it, and, moreover, the followers of Broussais must own that it is more a negative than a positive term, and rather expresses what the disease is not than what it is.

Let us now proceed to analyse the physiological doctrine. The first of Broussais's medical propositions is, "*that life is supported by stimulants, and that everything, which augments the vital phenomena, is stimulant.*" Now you are aware that the doctrine of the celebrated Brown was, that all diseases could be reduced to one of two expressions, viz. sthenic and asthenic diseases, a division which merely repeats in other words the strictum and laxum of the ancient authors. I have before told you that Broussais divided diseases into those in which a plus or minus degree of vitality existed, and in this way got rid of the specific diseases; you will at once then recognise in the doctrines of Broussais the opinions of Brown, and, in fact, the physiological doctrine is nothing but modified Brownism. Still the modification is of the utmost importance, and is that which gives character and value to the opinions of Broussais. Brown divided, as I have before stated, diseases into two classes, sthenic and asthenic; but observe, with him these are general terms, *applying to the body or system at large*. He did not conceive that one part of the body could be in a state of sthenia and another of asthenia at the same time, he merely recognised the two diatheses or general states of the economy, and disease was with him the result of a general condition either of exaltation or diminution of the whole sum of vitality. Now the peculiarity of the physiological doctrine is this, it admits the sthenia and asthenia, but applies these terms not to the whole economy, but to the separate organs as the case may be. Two of its most important propositions are, 1st. "that there is no such thing as a general exaltation of the vitality of organs (the sthenia of Brown) or a general diminution of this vitality (asthenia) but that we may have sthenia of one organ or system, and asthenia of another." 2ndly. "That all diseases are primitively local." "Health," says Broussais, "results from the regular exercise of functions, disease from their irregularity, and death from their cessation."

This leads us to another peculiarity of the physiological doctrine, and that is its exclusive solidism. Disease being the result of irregularity of functions, and functions depending on organs, and these organs being the solids of the body, it follows that in the solids alone we are to look for the sources of disease. To admit disease as primitively occurring in the fluids would be inconsistent with such opinions, and hence all diseases of fluids, and every remnant of the humoral pathology are carefully excluded from the system of Broussais. This is an example of a mode of proceeding

not unfrequently observed among medical as well as all other theorists. For instance, I have made a specious and pleasing theory, which I look upon as complete and perfect in all its parts; here is an alleged fact, but it must not be true because it is inconsistent with my theory; I will therefore get rid of the difficulty by denying it at once.

The follower of Broussais is then an exclusive solidist. Is this right? Are we to neglect the study of the alterations of the fluids, and are we to regard them as foreign to the economy, and holding no connexion with the phenomena, of organic vitality? No one denies that what has been called the humoral pathology contains a vast quantity of error, of unmeaning terms, and false conclusions. Yet we cannot expect much when we reflect on the low state of physiology and pathological anatomy, at the time this theory was in its highest vogue. Besides, there can be no doubt that anatomists, captivated with the discoveries of the last half century in the morbid anatomy of the solids, have gone too far in rejecting the humoral pathology altogether. The excitement which followed the dawn of chemical illumination in the first instance, and that consequent on anatomical discovery in the second, have now subsided, and it is found that truth lies between the anatomical and chemical theories of disease. In fact, to understand disease we must study the composition and structure, not only of the organised parts of the body, but also of those in which organisation cannot be demonstrated. Exclusive solidism can never explain all the phenomena of disease, and exclusive solidists can only know a part of the human system.

The illustrious Bichat, in his *General Anatomy*, says, that notwithstanding the exaggerations of the humoral pathology, yet it has some foundation in truth, and that there are many affections which can only be referred to an alteration of the fluids. On the subject of the fluids, it seems to be satisfactorily proved, 1st. That there is no exact line of demarcation between them and the solids. Who can say where the fluid ends and the solid begins? 2ndly. Many circumstances go to prove the influence of the nervous system on the blood. 3rdly. The composition of both is extremely analogous; fibrine, albumen, colouring matter, and salts are the constituents of both. Nay, many more of the secretions are found to exist in the blood. 4thly. The anatomical disposition is the same in both; the globules combined with an amorphous substance. 5thly. We find a red and white substance in both. 6thly. The effects of disease are similar, removal of red parts, and increase of albumen. Lastly, I shall quote on this subject Andral's three propositions. In the first place, he says, "As the solids are nourished by the fluids their composition and quality must be influenced by the fluids." Secondly, "As one class of solids is employed in making blood, that blood must be influenced by the state of

these solids." Thirdly, "As another class of solids takes from that blood, it is plain that these solids must also influence the composition of that blood. Hence it follows directly that the slightest alteration of the fluids will affect the solids, and the slightest alteration of the solids will affect the fluids." If, in addition to this, we recollect that there is no exact line of demarcation between the solids and fluids, that the chemical composition, anatomical character, and physical disposition are almost the same; and, lastly, if we admit the vitality of the blood, we must concede that the disputes between the solidists and fluidists are unnecessary, and that the animal body is to be looked upon as a closely connected whole.

Broussais was then wrong in rejecting altogether the humoral pathology, and this rejection it was that led to the greatest mistake in his doctrine, namely, that connected with the pathology of fever. If the alteration of the fluids causes disease of the solids, then the proposition that all diseases are primitively local must fall to the ground. He would not have erred so much if he had said that many of the diseases, which are supposed to be general, are in their commencement local. In this case he would not have committed himself too far, and it would have been a task of considerable difficulty to disprove his proposition. But he was led away by the ambition of theorising, and the statement that all diseases were originally local, was necessary to uphold his theory of fever. Time and the stubborn evidence of facts have tended to throw not only doubt but discredit on this theory, and Broussais has had the mortification of seeing his valuable labours but slightly appreciated, or even slighted, in consequence of their connexion with an unstable doctrine. Medical men saw that the fabric was unsubstantial, that it could not bear the scrutiny of a just and rigorous examination, and without looking to the intrinsic value and beauty of its materials, they pronounced the whole to be worthless.

So far, gentlemen, we have touched on the doctrine of Broussais, and exhibited some of its leading features. We have seen, that his rejection of the humoral pathology, his exclusive localisation of disease, and pure solidism were fatal to his system.

At our next lecture, when we shall enter on the consideration of local disease, we shall find that Broussais has given, with respect to the head, chest, and abdomen, some of the most beautiful and scientific principles of treatment that were ever promulgated.

A MEMOIR ON INOCULATION OF THE POX.

BY PHILIPPE RICORD, D.M.P.,

Surgeon of the Hôpital des Vénériens, Professor of Operative Medicine and Clinical Lecturer.

READ AT THE ROYAL ACADEMY OF MEDICINE

On the 4th of June, 1833.

Translated and now published for the first time, with an Appendix, by the permission of the Author.

BY ALEX. THOMSON, M.B., OF ST. JOHN'S CAMB.

GENTLEMEN,—In a first essay, which you were kind enough to receive favourably, and which had the honour of being inserted in the collection of memoirs chosen by you, I promised to bring you the result of my observations. I propose to accomplish this promise to-day, entreating, as then, your indulgence and encouragement.

The venereal disease, owing to the specific nature of my situation, is again the subject of this memoir, which will perhaps furnish you with some new and interesting results. But before entering on the subject, permit me to assure the learned Academy, which is kind enough to give me a hearing, that I am anxious to be sparing of its time, that I come not here for the purpose of making a display of erudition, which it possesses in a far higher degree than myself, and that, as regards my small efforts, I shall not turn over the dust of past ages, or engage in the controversies of the present day. I am about to relate my experiments, my personal observations, state what I have remarked, and indicate what I am still seeking. Doubtless in this paper all will not be new, for, I repeat it, I have rather observed the patient, I have rather sought for the results of experiment than for the opinions of others.

Of all evils afflicting the human race syphilis is the most insidious. It is in the very bosom of pleasure, it is in its very essence that it attacks man, frequently destroying the most fascinating illusions by the bitterest sufferings, what difficulty in avoiding it with its treacherous exterior, what incitement, and what occasions of becoming its victims! also what anxiety and what numerous researches to unveil, and how many labours to conquer it! Yet have we been always able to tear away its mask, or to chain its steps? All prudent observers will doubtless answer in the negative, and agree that all is not perfect in this twofold acceptance of the term. Is there not, even in the present day, a contest about the nature of pox (*verole*) and the symptoms characterising it? Does it not occur to the ablest men every day to be deceived? and is it not notorious that M. Bielt, so deeply skilled in the knowledge of skin diseases, admits the possibility of the error so easy to fall into, and so frequent in

the different diagnosis of herpes and of chancre. On the other hand, the words syphilis (*syphilis*) and pox (*verole*) are they not too general in their application, and do they not comprehend things differing in nature? In a word, is the venereal disease a single and identical affection, presenting itself under different forms? or else, on the contrary, are the pleasures of love, whether pure or impure, the sources of different affections? and of these affections are there not some that arise almost spontaneously, and without suspicious origin? One part of the question is already settled; but all the parts are not so; and yet their resolution is of the highest importance. These are frequently questions not only of pure pathology but, moreover, of morality. Has an individual venereal? Yes, or no? Such is the question to which we must every day answer, to save the honour of a person unjustly suspected, or to determine the prospects of another; and this it is expressly, which frequently cannot be decided. But, without dwelling longer on general considerations, and mindful of the promises, with which I set out, not to abuse the precious moments of the Academy, I shall forthwith point out the nature of my researches and their results.

1st. Pox is contagious. This is a truth we are unhappily obliged to admit.

2nd. This character (contagion), which is one of those peculiar to it, does not belong to all its forms.

3rd. In this respect, the differences are such as would rather induce one to admit diseases, essentially different, in what have hitherto been regarded but as forms of an identical affection.

4th. Finally, can the operation of mercury be well determined in the symptoms called primitive and secondary? is it a medicine simply curative of the existing symptoms, or is it at the same time a prophylactic remedy?

Observations have not been wanting since its terrific birth, whatever may be the land of woe that brought it forth, to prove the contagious nature of the pox. But it must be owned, even in our times, that the observations collected from patients have always been deficient in precision. Thus, when it is said that a woman, affected with blennorrhagia, has given chancres to a man, had that woman, to determine that she had only blennorrhagia, been examined with the speculum, as I examine them in the present day? Had the eye passed in review the whole extent of the organs of generation from the vulva to the uterus? No. Hence have errors glided into the study of syphilis, regarding the coincidence of its symptoms, and the manner in which they are propagated from one individual to another.

To facilitate the study of the pox, in regard to its intimate nature and its prophylactic and curative treatment, attempts at inoculation have been made at different periods, but hitherto have been tried only from diseased individuals, or from diseased individuals to

animals, and yet they have not been able to be well followed up, or generally applied, in spite of the experiments of Luna, Calderon, and some young French medical men, of whom the melancholy history is not forgotten. Never can it be tolerated in a professional man, however praiseworthy his intentions, to convey to any whomsoever in health, a disease for the sake of studying it, and least of all a disease of which the consequences may be so serious; and yet, in order to emerge from the chaos, to escape from the errors so easy to fall into, induced by the statements of patients, so many of whom designedly deceive you, while others deceive themselves, inoculation, that invaluable criterion, ought still to be employed, the only question being how to employ it with the least danger.

A patient affected with a lesion deemed syphilitic, whatever may be its nature, is still susceptible of contracting another; thus, after a first cotion, he may be seized with a blennorrhagia, and by a second contact, a chancre. Chancres on different points may be contracted in different connexions and at different periods; thus: it is not uncommon to see women, already affected with chancre of the vulva, receive, at a subsequent period, a new affection of the anus, while the first still exists. Successive chancres, or inoculation of the adjacent parts, of wounds, of leech bites in the neighbourhood of chancres, are observed daily.

These observations, which had been made before mine, which have not always been explained in the same manner, could hardly have escaped my notice; and on the other hand, I knew that the danger of the pox was not in a direct and constant ratio with the extent and the number of primitive lesions. Hence, I drew this conclusion, that an individual, already deemed venereal, runs no risk from an inoculation, for which he himself furnished the matter, seeing that, under all circumstances, nothing could be given him, but what he already laboured under.

This principle being fixed, I commenced some experiments in the first months of the last year, and soon determined to follow them up regularly; all of them have been performed at my clinical visits, and have been witnessed by a great number of pupils, who attend my visits and lectures, and by many medical men.

Having taken the lesions deemed syphilitic one by one, and inoculated the individuals already labouring under them with the different products of their secretions, we have recognised this truth already established, that the symptoms called consecutive are not contagious, and that among the primitive, there exists great difference in this respect, as will soon be seen.

To practise the inoculation on the individual himself, I have taken pus, puriform mucus, and all the morbid secreted substances considered to belong to venereal affections, and have conveyed them, by the aid of the

lancet, under the epidermis of the inner part of the thighs, or upon leech bites of different durations, or upon parts of the skin, rubified or blistered, in different manners, or, finally, into the bulbs of hairs, these having been previously torn away. The puncture of the lancet has proved to be the most appropriate means for chancres and primitive lesions of the same nature.

When the inoculation has succeeded, it has given rise to a *characteristic pustule*, which we have never been able to produce by any other means, and which we shall now describe.

The first day, that is to say, twenty-four hours after the inoculation, a slight redness and a small elevation indicate the point at which the puncture has been made. On the second day the point becomes more elevated, surrounded with an areola, and assumes the conical form of a small pimple, of which the summit is crowned with a black or brown point, formed by dried blood, the results of the inoculating puncture. On the third day the epiderm is raised by a semi-transparent serosity of a yellowish colour, and which already existed in small quantity on the second day, constitutes a small pustule. On the fourth day this pustule becomes elevated assumes a round form, and the central blackish point is sunk, so as to form for it a species of umbilicus.

The areola, hitherto rather extensive and of a more or less vivid red hue, has now a tendency to become evanescent, in proportion as the liquid inclosed in the pustule is transformed or becomes purulent. On the fifth day the tissues adjacent to the base of the pustule are engorged and hardened. After the sixth day the pus thickens, the pustule is puckered and dries up, a stratified crust is formed of unequal discs, of which the smallest are at the summit, while the largest occupy the base. This crust may remain for a long time adherent, and even until such time as the subjacent parts be cicatrised, or may fall sooner or later, either spontaneously or by artificial means; and then it lays open an ulcer, having all the characters of the primitive venereal ulcers, known by the name of chancres.

When the inoculation is to give no result, the point punctured by the lancet having reddened during the first twenty-four hours, all trace of it disappears on the second day; so nothing remains but a small irregular pimple, which soon disappears, without ever presenting the character we have attributed to the characteristic pustule. In all our patients three inoculations have been made at once. When the symptoms have been of a nature to be inoculated, never has a single puncture failed in the great number of experiments made during two years; it has not occurred to me, for instance, to see two pustules only developed when three punctures have been made, or four or five when six

have been made; all or none is what I have always seen.

In the cases in which the inoculation has not taken, I have repeated it two, three, four, and five times with the lancet; then by the aid of leech-bites, so easily to be inoculated with chancrous matter; then by rubefying the skin, by vesicating it with cantharides or ammonia; then in the bulbs of the hairs, these having previously been torn out.

I have inoculated by the means I have just indicated—

1st. The matter of chancres, and of all ulcerations of the organs of generation, of the anus, and of the adjacent parts in the man, and in the woman.

2nd. The matter of urethral blennorrhagia in the man, of vaginal and uterine blennorrhagia in the woman, and of anal blennorrhagia in both.

3rd. Pus of buboes in different stages.

4th. Matter secreted on the surface of mucous papule or pustules.

5th. Pus of ulcerated tubercles.

6th. Pus of ecthymatous pustules.

7th. Secretion of the *ulcus elevatum*.

8th. Matter from ulcerations of the neck of the womb.

9th. Matter from ulcerations of the lips, of the internal walls of the cheeks, and of the throat.

10th. Pus furnished by carious bones.

11th. Matter secreted by the different excrescences and vegetations.

12th. As a counter proof, I have inoculated venereal individuals, or those I have considered such, with scrofulous, phlegmonous, herpetic, and acneal pus, with ichor of cancer, and of gangrene. Leech-bites also, and punctures of unsoiled lancets, and operations have been practised during the existence of well-characterised primitive symptoms.

The following are the results I have obtained:—

1st. Pus, taken from ulcerations having all the characters of chancre, has produced the pustule, not only once in the same individual, but three, nay even six times. The matter of these pustules, introduced by inoculation in its turn, has furnished pustules similar to those from whence it has been taken; and the last in their turn have occasioned similar pustules. I have produced as many as five generations, and I could have produced more still from the last, had I desired it: never have accidental pustules similar to those of inoculation supervened. Chancre has been inoculated in different stages of its progress, and unless there have accrued neutralisation, transformation, or change of its principle, the inoculation has constantly succeeded.

2nd. Ulcerated buboes of five, six, and seven months' duration, and not having produced consecutive or general symptoms, have still given rise to the inoculation. The chancre, which at first furnished a characteristic pustule, may be neutralised under the influence of a

spontaneous effort at cure, and be no longer contagious; while the pustule it has produced is still so. Here care must be taken against a cause of error. Dried pus, of the period at which a chancre was inoculable, may be taken from the sore, in place of that which is being actually secreted, and which is no longer so*. Chancre may be neutralised by a general or local treatment; and finally, it may be transformed, *in situ*, into a consecutive ulceration, assuming its peculiar character, being then no longer contagious, the essential character, specific of primitive chancrous ulceration, being *inoculability*.

3rd. Suppurated bubo may give rise, by means of inoculation, to the characteristic pustule, in circumstances that are curious and important to examine.

a. When there was suppuration of one or several ganglia, when the skin placed over them had ulcerated after a spontaneous or artificial aperture, and when the bubo was subsequent to a chancre, the pustule always occurred.

b. The same thing took place when suppuration had been established in a lymphatic vessel; thus, there is identity for lymphitis and adenitis, the consequences of chancres.

c. When the inoculation was made, at the moment, of the aperture of the bubo, which we shall name *purulent lymphatic*, for the purpose of distinguishing it from phlegmonous, scrofulous, and simple lymphatic buboes, it has often failed, but, after some days, succeeded.

d. When the cellular tissue alone has been attacked with suppuration, whatever may have been the origin of the bubo, no ganglion having participated in this suppuration, although tumefied, and even prominent, through apertures made in the skin, inoculation has produced nothing; whence we must draw this conclusion, that the matter of chancre, or the *virus*, as they would have called it, is transmitted by means of the lymphatics, and remains imprisoned there until an ulceration from within outwards, or suppuration, makes a passage for it.

4th. Blennorrhagia gives also the characteristic pustule equally with the chancre; but, in this case, the most uncommon, it may be concluded that it is due to a chancre of the canal, for, in the others, never does it give anything, at least by the lancet, leeches, or recent wounds.

Never has blennorrhagic matter, taken in a vagina examined carefully by the aid of a speculum, and in which there has been found no chancre, given the pustule. In three cases

* M. Vernois, one of my *internes*, has been requested to preserve some crusts and pus in tubes and between glass plates, in order to ascertain how long they may preserve their contagious character.

only, hitherto, of urethritis in men, without the least external excoriation, or any visible ulcer, in which matter had been taken from the meatus urinarius, which was not ulcerated, as far at least as the sight could reach by known means, has the characteristic pustule been produced, although the inoculation was performed twice at different periods, and with three punctures each time.

Such, gentlemen, are the only lesions deemed *primitive venereal*, which have furnished, by this mode of investigation, a character common to them, and specific, making them into a distinct disease—I mean the pustule we have been describing above.

All the lesions deemed venereal, studied in the same manner, have constantly yielded us negative results. They will hereafter form the subject of a distinct essay. But before terminating this, let us examine what are, up to this period at least, the consequences that may be deduced from it.

1st. Do not the results it furnishes to us explain the differences of opinion existing in the contagious nature of pox?

2nd. Chancre, and the lesions directly dependent on it, alone giving rise to the pustule we have described, constitute a disease altogether distinct from the other lesions called venereal.

3rd. Ulcerations having the same seat, and nearly, if not altogether, the same aspect, furnishing analogous secretions, and having an origin equally suspicious, may essentially differ from one another, inasmuch as some are contagious while others are not so*.

4th. Thence, an ulceration being given, it is impossible to say, from its seat, its aspect, and the apparent nature of its secretions, in a host of cases, whether it be a virulent chancre or a simple ulceration of a chancreous form; in fact, a pseudo non-contagious chancre.

Inoculation, in whatever manner practised, can alone solve the difficulty; and this question will be very often of importance to decide, whether in legal medicine or in a multitude of other circumstances, as for instance, in the following, which has very often occurred to more than one medical man.

A husband returns from a voyage; after suspicious connexions, ulcerations have supervened on the genital parts; he has marital

duties to fulfil; if he abstains too long from doing so he may trouble the peace of his fire-side; serious consequences may ensue. Well, then, is it not important to be able to decide whether or not his ulcerations are contagious, and whether he may or may not have connexion with his wife?

5th. Very extensive primitive ulcerations may pass into a chronic state, and persist for a long time, without determining consecutive symptoms, and preserve their pathognomonic character, namely *contagion*.

I have at this present moment in my wards some ulcerated buboes of which the ulcerations have acquired a great extent, which have given rise to no consecutive symptom, after a duration of five, six, and seven months, and which still preserve their contagious or inoculable character.

6th. Other ulcerations, as we have already said, after having been contagious, speedily cease to be so, whether they do or do not progress towards cure.

7th. A wound may be made in the neighbourhood of a chancre already existing for a long time, without becoming venereal, provided it be not touched by the pus coming from that chancre.

8th. All chancres are far from producing buboes. Their production requires certain relations to exist between the chancres and the absorbent extremities. Hitherto our pustules have never determined buboes †.

9th. There is no general infection from chancres in the primitive state, or production of new contagious chancres, after the existence of a first, without a new inoculation, whatever may be the mode of its origin.

10th. Ulcerations, excepting of the inoculation, or other lesions regarded as consecutive upon chancre, are not contagious, unless they proceed from a ganglion or lymphatic vessel directly infected, and suppurated in consequence of a chancre, which then constitutes in my opinion an ulceration *successive* and similar in nature.

11th. From our researches, ulcerations of the mouth, throat, and every other part, susceptible of yielding inoculation, enter into the category of other chancres, and differ essentially from the ulcerations of these parts called *consecutive*, with which they have then no relations but of form and seat.

12th. From these first essays, and from the decided differences, they have enabled me to establish between certain lesions, which hitherto bear the common name of pox (*verole*) or

* This I deny; and I refer the reader to the characters I have given in the supplement, of the ulcers producing the pustule on inoculation, in proof of my opinion. I have never seen, during the four months I have followed up the experiment of M. Ricord, one single ulcer, capable of yielding an inoculable pustule, which did not present the whole of these characters, provided it were seen before coming to its *maximum* of intensity; for, after this, during the tendency to heal, form and colour cease to be fixed characters for this or for any other form of ulcer.—A. T.

† This is incorrect. I have never seen suppurating buboes as the result of inoculation, but I have seen out of some hundred experiments, both on men and women, few cases in which the vertical ganglia arranged parallel to the saphenic vein have not been considerably enlarged, painful, and indurated, without, however proceeding on to suppuration.—A. T.

syphilis, have we not the right to conclude that if mercury be a specific for one of these lesions, it may very well not be so for the others, and to explain its successes and its failures, thus making up the difference between those who approve and those who disapprove its use.

18th. Finally, if while waiting for the result of the researches we are making on the other lesions referred to the venereal disease, we have been enabled to advance, with the engagement to prove, the foregoing propositions, we have caused an advance to be made in the science, by throwing light upon some points hitherto very obscure, and by publishing some truths of the highest importance, such for instance as the contagious nature of certain ulcerated buboes, though it has just been published in a recent article* in the *Nouveau Dictionnaire de Médecine Pratique*, "that the pus of all buboes may be inoculated with impunity." I challenge the authors of that article to inoculate themselves with the pus they deem so inoffensive, while I offer to submit myself to the inoculation of all the lesions I announce as uninoculable.

Gentlemen such are my labours, my observations have not been made with closed doors, and may be relied on. If you deem them useful, your approbation will sustain me along the painful path I have to follow, and from which I shall not be deviated by the cry of those I may leave in the rear. If I arrive at my object, or only approach towards it, those men who have judged before hearing me will alone bear the weight of their judgments.

APPENDIX TO THE PAPER OF DR. RICORD.

Containing the result of observations on his Experiments during four months' attendance on him at the Venereal Hospital, in the spring and summer of 1833.

BY ALEX. THOMSON, M.B. OF ST. JOHN'S CAMB.

Characteristic Pustule resulting from the Inoculation of Syphilitic matter.—By what matter produced.

1st. In no case, but two, has matter from an anal, genital, balanitic, preputial, urethral, vaginal, labial, nymphyal, tincal, intrauterine, or cutaneous ulcer, having a more or less indurated base, hard, elevated edges, perpendicular to the bottom of the ulcer, and the bottom

of a greyish white, or greyish yellow colour, failed of being followed on the first inoculation in the skin of the thigh by the characteristic pustule.

a. One exception occurred in anal sores having these characters, so that it was taken for syphilis communicated per anum. The history of the case was doubtful, and the inoculation was not repeated. He had similar sores upon both the anterior faces of the anterior palatine pillars, and many ulcers, considered by M. Ricord secondary, in the mouth and pharynx. The anal and palatine pillar ulcers healed more quickly even than the others under the use of protoioduret of mercury. This case has already been published by Dr. Ryan.

b. The other was in an itch patient, in whom the ulcer was the result of an itch pustule scratched upon the internal malleolus, and had been taken for a secondary ulcer by M. Dupuytren. It was rapidly cured, and produced only a pimple without a vesicle, and without pus on inoculation.

2nd. In no case whatever has pus taken from ulcers wanting the characters described in No. 1, or particularly the greyish yellow, or white bottom only, been followed, even after numerous inoculations with the lancet, or on leech bites, by any pustule whatever†.

In two or three cases, ulcers, both cutaneous and genital, have had hard elevated edges, perpendicular to their bottoms, and even of a blueish-red hue, but with their bottoms reddish, and more or less granulated, and in none has the pus yielded by them been followed on inoculation by any kind of vesicle.

3rd. In no case has pus taken from an inguinal bubo accompanying any of the ulcers mentioned in No. 1 failed, after the bubo has been opened from one to three days, to be followed upon inoculation by the characteristic pustule.

In no case, where the bubo has been opened in the hospital, has the pus let out by the first incision, or discharged during the first or first two days, been followed on inoculation by the characteristic pustule.

4th. In no case has anal, balanitico-preputial, urethral, vaginal, or intrauterine pus, or gonorrhoeal discharge, when accompanied with such sores as described in No. 1, in the parts corresponding to, or traversed by, the pus,

* By MM. Cruveilhier and Rattier, one of the most flagrant articles ever written by medical men, in which M. Rattier abuses M. Ricord's experiments, and declares them false, without having ever seen them but once, and that in my presence, when he declared publicly that he had never seen any similar experiments, and when he displayed the most complete ignorance of the subject—A. T.

† M. Ricord assures me that he has since then seen some, in which the grey bottom had actually disappeared, and which still yielded inoculation, although the external characters of chancre had previously existed. This is very important, as the patient may apply for relief when all external characters of chancre may be lost, and when nothing but inoculation can determine its character.

failed upon the first inoculation of yielding the characteristic pustule.

5th. In no case has the pus of inguinal bubo, accompanying anal, balanitico-præputial, urethral, or vaginal pus, that has been followed on an inoculation by the characteristic pustule, failed of being succeeded on inoculation in the same circumstances as the buboes mentioned in No. 3, by the characteristic pustule.

6th. In no case has the pus of inguinal bubo not successive upon the ulcers mentioned in No. 1, nor upon pustule generating vaginal, urethral, anal, or balanitico-præputial pus, been succeeded on inoculation by the characteristic pustule, or by any pustule whatever.

7th. In no case has pus taken from a characteristic pustule failed of being followed on the first inoculation by a similar pustule.

8th. In no case have leech bites, or scratchings come in contact with matter from such sores as described in No. 1, or the pus of these sores scattered over the bed, or the pus mentioned in No. 4, or with pus from the characteristic pustule, failed of being converted into the characteristic pustule.

M. Rattier, the externe of M. Ricord, assures me, and M. Ricord confirms his observation, that when the pox matter comes in contact with a very largely open leech bite, a chancre is directly formed, without the characteristic pustule.

Inoculations of Syphilitic, or rather Chancrous Pus.—Its Consequences.

1st. Invariably followed by the characteristic pustule described in Dr. Ricord's memoir.

2nd. In no case has the pimple, areola, pustule, crust, ulcer, or cicatrix assumed any other form than that of a circle, or ellipse, the last of which is rare, and in both of which the puncture forms the true central point.

3rd. In no case has more than one pustule followed upon each inoculation, or arisen from the same areola.

4th. In no case has a pustule arisen from the areola alone, without including the puncture.

5th. In no case, although in general there has been no more space between each two punctures than an inch in diameter, has a pustule arisen in that space.

6th. In no case has a pustule arisen in any other part of the surface of the body at the same time with the pustules from inoculation, unless it have been clearly traced, that pus from the original or factitious ulcers produced by inoculation, have in that part touched some abraded surface.

7th. In no case has one or more out of several inoculations taken without the rest.

8th. In no case, where there has been more than one inoculation, has one marched, or tended, or become incrustrated, or been formed into an open ulcer, when left to themselves, or healed more rapidly than the others.

9th. In no case has an ulcer resulting from

an inoculation extended to more than one inch, and in scarcely any to less than three quarters of an inch in diameter.

There has, however, occurred during my attendance, one case of a barber who had had chancre of a serpiginous character in the groin during nine months, in which all sorts of treatment had been employed in vain during that period in the hospital. He was inoculated at my request, when the pustules ran their usual course; but, towards the 30th day, began to run together, and finally formed a serpiginous ulcer, of about six inches in vertical by three in transverse diameter. After two months' vain treatment of various kinds, cicatrisation commenced in the centre, and is now proceeding towards the circumference, while the circumference is expanding under the influence of the ulcer.

M. Ricord has since had another case, entirely similar, in which cicatrisation has not yet commenced, and which leads him, with the last, to suppose that there is some constitutional peculiarity in those in whom chancres become serpiginous, as in no others have the inoculation ulcers assumed such characters. In neither of these cases, the one thirteen months, the other seven, in the hospital, have secondary symptoms occurred.

10th. In no case has the pus oozing from the pustular ulcers, or from beneath the crusts, though trickling over and drying upon the thighs, been followed by a pustule, although the same matter has been followed upon inoculation by similar pustules.

11th. In no case have the ulcers from the inoculations been cicatrised, either during mercurial or antiphlogistic treatment, previously to the cicatrisation of the original ulcers.

12th. In no case when inoculations have been made with the pus of inoculations about to heal, although but twenty-four hours before the termination of the cicatrisation, has that pus failed in reproducing a similar pustule and ulcer.

a. Yet I have seen them made thus, as the cicatrices were on the point of closing in the same subject successively for four generations, and yet be produced in an equally marked manner from the last.

b. I am assured however, by M. Maxime Vernois, interne of M. Ricord, that one case has occurred to him, in which three successive inoculations had been thus made, and in which the last, some time previously to being healed, yielded nothing upon inoculation effected in several different manners. M. Ricord distinctly remembers this case, and assures me that the patient was under a mercurial treatment when this curious fact was observed.

13th. In all the cases the development of the inoculatory pustules has been followed by

more or less uneasiness, induration, and pain, and in three, by considerable pain, enlargement, and induration; but in none by suppuration of the vertical series of superficial inguinal glands lying alongside of the head of the internal saphenous vein.

14th. In no case has ulcerated sore throat, or tubercular or erythematous eruptions supervened during the existence of these pustules, though many of them have been open without treatment, save repose and half diet, for the space of from two to three months.

15th. In no case, during my stay at the hospital, did one that presented itself with secondary symptoms at the weekly consultations, prove to have been among those inoculated during the last two years.

We may therefore fairly conclude, since secondary symptoms did not display themselves in persons retaining these ulcers for three months, and since, during the space of two years, none of those who had been inoculated presented themselves with secondary symptoms, that those inoculated are not more liable to secondary symptoms than others, or that the number of chancrous ulcers is no scale of the probability of secondary symptoms.

16th. In several cases there have been inflammations of the contagious absorbent vessels, immediately upon the inoculation, to the distance of two or three inches from the inoculated points, which have, however, always ceased in a day or two, without any serious consequences, and without the application of any treatment.

17th. In no case have the ulcers or pustules, the consequences of inoculations, been followed by more than itching or a slight prickling pain.

18th. It is universally worthy of remark, that the cicatrices of the ulcers, resulting from the inoculation, were not followed by contracted or radiated marks, but by a regular round elliptical spot, equal in size to the ulcer, level with the surface of the skin, and more or less copper-coloured for some weeks after the healing of the ulcer.

Characters of the characteristic Pustule, Areola, Crust, and Ulcer; according to the days, from actual observations. As deduced from cases taken down by Alex. Thomson, M.B.

1st day. Inoculation with the matter by a lancet puncture on the inner part of the upper third of the anterior surface of the thigh.

2nd. Puncture surrounded with an areola, gradually but extremely slow, elevated towards the centre, redder than the skin, and becoming more intensely so towards the centre; from half to three quarters of an inch in diameter, perfectly and regularly round, or elliptical, having a portion, immediately around the puncture, much redder and more abruptly elevated, harder, and from one-eighth to one-tenth of an inch in diameter, and already sur-

mounted with a pustule one-half to three-quarters of a line in diameter, and already containing semi-opaque yellowish-white matter (pus), and itself surmounted with a central spot of coagulated blood.

3rd. Areola increased in magnitude, about three-quarters to one inch in diameter, having a pustule in the centre about one to one and one-half lines in diameter, flat at the apex, and depressed with a dark spot in its centre.

Yet this depression does not occur in more than two-thirds of the cases, and is therefore not characteristic.

4th. Areola unchanged in size; pustule one-third larger in diameter, having its base much larger, harder, and more elevated, and of bluish red hue.

5th. Areola unchanged; pustule more distended, about one-eighth of an inch, and with its indurated base one-third of an inch in diameter.

6th. Areola diminished about one-third in diameter; the base of the pustule increased about one-third in diameter, harder, blue, elevated about a line above the skin; pustule itself flatter, and nearly on a level with the summit of its base, and having, at its centre, equal to one-third of its diameter, a greenish brown crust.

7th. Pustule replaced by irregular reddish brown crusts, about one-third larger than themselves, or about one-fourth of an inch in diameter; areola much indurated in the subcutaneous cellular tissue, increased in elevation, so that they form a cone of a faint bluish-red hue, gradually rising from the margin of itself to the margin of the elevated edges of the withered pustule.

8th. Areola equal in size, less indurated, and faintly red in place of blue; the pustule reformed, the crust forming a part of its coverings, which is sometimes again burst, while the crust begins to form a saucer-like cavity upwards. This reformed pustule generally contains sanious coloured pus, or chocolate coloured pus.

9th. Areola unchanged in magnitude and appearance, but paler in hue, and having much less subcutaneous hardness; having the pustules, reformed the day before, flat indeed but about half an inch in diameter, now containing yellowish pus, and having about the central fifth of their skin formed by yesterday's crust; the transparent part of the coat being now divided by furrows, radiating from the crust to the circumference, as in small-pox. The pustules at this period frequently rupture, and are reformed, the dry pus forming the successive layers of crust.

It is about this period, or the few subsequent days, that pricking, or slightly lancinating pains begin to be felt in the base of the pustule.

10th. Areola entirely disappeared, and converted into a pustule about three-quarters of an inch in diameter, and about one and one-half or two lines prominent from the skin, containing

a watery translucent pus, but similar in other respects to the pustule of the last stage.

11th. Pustule replaced by a dark reddish-brown crust, formed of a series of layers, concave towards the observer, and successively larger from him towards the skin, all irregular in the margin, and successively thicker from the observer to the skin, allowing, when pressed upon, a greater or less quantity of watery pus to ooze from beneath the edges of the crust, which is sometimes sanguinolent, sometimes transparent and colourless, and sometimes chocolate coloured.

12th. Inoculation crusts in the same state, but thicker, broader, blacker, and permitting a thicker pus, tinged with blood, to ooze from under it when it is pressed.

13th to 16th. From time to time lancinations and prickings are felt beneath the crust, which increases much in size, becomes more cupped or concave in the middle, more elevated, and more rugose towards the edges, becoming surrounded by exfoliation of the epiderm, over a small adjacent space only.

17th to 19th. Crusts alternately becoming loose and adherent, permitting the escape of a brownish pus from beneath their loosened margins, being nearly an inch in diameter, and from two to three lines in height.

20th to 25th. Crusts increased in size about one-fourth, permitting the discharge of a fetid pus of a chocolate hue; lancinations still continuing.

26th to 34th. Crusts becoming loose and again adherent, remaining unchanged in appearance, but the oozing pus taking on a healthy character, of a yellow hue and creamy consistence.

34th to 36th. The crust falls off of its own accord, displaying an ulcer equal in diameter to the original areola, filled in part or altogether with large, pale red, fleshy granulations, isolated from one another on the surface, and soon covered with a reddish-brown crust, assuming the form of the granulations, and consequently having a blistered appearance, the edges of the ulcer being hard, blueish, and from one to one and a half lines in breadth. Sometimes the granulations are only arranged like beads around the margins of the cavity of the ulcer, leaving the centre flat and depressed from one to one and a half lines below their summits, and of a greyish-white or greyish-yellow hue.

From this time forward nothing constant can be established, except that where there are few granulations on the falling of the Ruppial crust, the ulcer is gradually filled up by smaller granulations, which become crusted, and if the crust is left to itself, which it has rarely been, is covered with a thin pellicular epiderm previously to its fall, but when poulticed, cicatrises slowly from the skin inwards, in both cases presenting at first a slightly prominent tumour, which gradually sinks as the patient recovers; and as the indurated edges of the ulcer return to their natural consistence

and level, although the cicatrix finally, if it have any peculiarity, becomes rather broader than narrower than the ulcer, remains upon a level with the skin, is smooth and unpuckered, and always retains more or less of a brownish red tinge.

It must be borne in mind, that my course of these pustules is deduced from cases purposely left untreated, except by repose and half nourishment, by Dr. Ricord, and cannot, therefore, be looked upon as the course of those that are poulticed at an early period, or touched with caustic in their progress. When the crusts fall from the application of a poultice, an ulcer similar in all respects to the chancre I have described at the commencement of this appendix, equal in magnitude to the original areola, is displayed, which follows all the phases of chancres, and is easily cured by the same means.

I have seen the pustule burst by a puncture during each of the four first days of its existence, and burnt with a sharp pointed pencil of nitrate of silver, and thus entirely arrested in its progress. An eschar is formed, which becomes hard, dry, and black, while the areolar redness and swelling gradually subside, and at the end of four or five days fall, leaving a cicatrix readily formed.

If it be asked why my observations differ from those of Dr. Ricord, I answer, because my cases were taken down minutely day by day at the bed side, that the generalisation of Dr. Ricord has been drawn from ocular inspection, chiefly aided by memory, and that Dr. Ricord, who has carefully perused with me the facts of this appendix, authorises me to state, that he recognises the accuracy of all the observations. In support of the accuracy of my results I have the cases, which I have been permitted to take down by Dr. Ricord, for whose urbanity, kindness, and liberality to all our countrymen, as well as to professional men in general, he deserves the utmost gratitude of our profession, as he does that of the public, for his unwearied, assiduous, and unexampled success in his researches into the nature of this Protean and insidious enemy.

Facts deduced from the consideration of Inoculation of Pox matter, leading to the belief of the existence of Chancre in the Urethra as the cause of the virulence of Gonorrhæa.

1st. In all cases, where chancre can be seen, its pus, or balanitic, urethritic, or vaginitic pus coming in contact with it, is invariably followed by the characteristic pustule.

2nd. In no case where the parts can be examined by the eye alone, or aided by the speculum, either immediately or when swelling and irritation have subsided, is balanitic or vaginitic pus, when unaccompanied by chancre, followed by the characteristic pustule on inoculation.

3rd. In all cases, where the parts are temporarily hid from inspection by original mal-

D D

formation, or accidental tumefaction, if the characteristic pustule have followed on the inoculation of the matter, chancres, or characteristic cicatrices have been found on the removal of the obstacles by art, or resolution.

4th. Even in the urethra, when urethritic pus has been produced or been followed on inoculation, by the characteristic pustule, in three cases chancre has been found in those parts to which examination can reach, as to the first three lines in the urethra of the woman, the first four or five lines in that of the man. It seems thence of the highest probability, that whenever urethritic pus is followed on inoculation by the characteristic pustule, there exists a chancre in the urethra.

5th. This idea is strengthened by the fact that in all the cases tried, and almost all have been tried, when visible chancre, accompanied by balanitic or vaginitic pus, has been cured previously to that pus having ceased to flow, that pus, though totally unchanged in all its external characters, has produced no pustules on inoculation. Add to this that

6th. Every bubo that has followed a chancre visible on any part of the genital or urinary organs, has, on its pus being inoculated one or two days after the bubo has been opened, (because bubonic pus scarcely ever, or rather never, gives rise to pustules on inoculation for a day or two after the bubo has been opened,) been followed by the characteristic pustule.

7th. Every bubo accompanying urethritic pus has occurred in cases in which there has been either visible chancre, or pustule yielding urethritic pus*.

8th. Every bubo accompanying urethritic pus has yielded, on the inoculation of its pus, characteristic pustules.

9th. In three cases of mere bubonic pus from the inner of the horizontal range of superficial inguinal absorbents, where there was neither anal nor urethritic pus, nor anal nor penial ulcers of any kind, yielded on inoculation no pustule at all.

10th. In one of these it is true the suppuration was not in the gland, but in the cellular membrane and true skin anterior to it†.

Hence it appears fair to conclude that,

Whenever genital pus, or pus from the genital or urinary organs is followed on inoculation by the characteristic pustule, there exists somewhere or other in these organs a *chancre*. In other words, that virulent gonorrhœa is simple blennorrhagia, accompanied

with urethral or vaginitic chancre. This is actually the opinion of Dr. Ricord, who has however some doubts yet uncleared up regarding gonorrhœa, when accompanied by mucous pustules.

Are these pustules, which appear simultaneously on the genital parts and skin, and in the mouth, the result of gonorrhœa, or of a constitutional affection, or of a peculiar and distinct species of blennorrhagia?

Reviews.

A Series of Anatomical Plates, in Lithography, with References and Physiological Comments, illustrating the Structure of the different Parts of the Human Body. Edited by JONES QUAIN, M.D., Prof. of Anat. in the University of London. Roy. fol. Fasciculus I. Two Plates.

A Series of Anatomical Plates, illustrating the Anatomy and Surgical Anatomy of the Human Body, with a Descriptive Text. By G. D. DERMOTT, Esq., Lecturer on Anatomy, &c. at the Medical School, Westminster Dispensary, Gerrard-street, Soho. Royal folio. One coloured Plate. Published by the Author.

BESIDES the two works before us, another is announced for immediate publication. We can no longer complain of the want and scarcity of British anatomical plates, and more especially as those under notice are admirably executed, and published at an exceedingly moderate price. In this important particular they have a decided advantage over other productions of this description already extant.

Few anatomists are so competent as those whose names stand at the head of these remarks to undertake and execute a series of anatomical plates. Professor Quain has afforded ample evidence of his profound knowledge as an anatomist by his popularity at the Aldersgate-street Medical School, and more particularly at the London University, where his clear, methodic, and comprehensive lectures have given the greatest satisfaction, and elicited the unanimous thanks of

* Yet, since these observations were written, M. Ricord has three cases in women in which there is vaginitic and urethritic discharge, and ulcerated inguinal bubo. The matter of none of these parts has produced inoculation; hence, proving in some measure the truth of the observation.

† M. Ricord has since had two exactly similar cases.

the largest class in this metropolis. His "Elements of Anatomy" is one of our best standard works, and is, in our opinion, infinitely superior to any monograph produced by his competitors in the London schools. Its greatest rival is that of Mr. Bransby Cooper. The various Manuals, Dissectors, &c., are generally good in their way, but not sufficient for the student who is advanced in anatomy, or as works of reference and authority.

In the present publication Dr. Quain intends to arrange a series of the most approved anatomical drawings, selected from monographic and systematic works, such as those of Scarpa, Tiedmann, Mascagni, Caldani, Cloquet, and Loder. Some of these works are extremely expensive, and totally beyond the reach of students and the majority of practitioners. Besides this objection, their text is in a foreign language. To remedy these objections, at the smallest expense, the present undertaking is commenced. The plates are accompanied by letter-press, containing minute descriptions of the tissues delineated, and the nomenclature is given in the English, Latin, and French languages. Physiological descriptions are also included. The number of plates will be about two hundred and fifty, and each fasciculus will contain two illustrations, with text. A fasciculus will be published every fortnight, at the surprisingly low price of two shillings.

The one before us illustrates the muscles in the erect and sitting postures, as also the general anatomy or proper tissue of muscle. The plates are well executed, the descriptions concise and comprehensive, and the typography of the first order. The work is highly creditable to the well-earned fame of the author, is extremely useful and instructive to students and practitioners, and does honour to the Institution to which he belongs.

Of the second fasciculus in our list we can speak in terms of high commendation. Mr. Dermott is well

known to the profession as one of the best and most successful lecturers on anatomy in London, and his numerous pupils are to be found in every part of this and distant countries. He has already published a series of anatomical plates on a large scale, which were favourably received by the profession. In the present series, he comprises the descriptive and surgical anatomy in each plate; and when we state, that he has, in one coloured illustration, included the anatomy of the head and neck, at the trifling expense of four shillings, we need scarcely say, that we strongly recommend his work. If he go on in this way, as we believe it is his intention to do, he will illustrate the anatomy of the human body on lower terms than ever before attempted. When we inform our readers, that in one view they may see the muscles of the face, scalp, neck, the arteries, veins, and nerves, with a description of all on the opposite page, and especially of the surgical operations connected with this important region of the body, and on such low terms, we think there is reason to infer, that a few plates will illustrate the whole system at a trifling expense. The work is comprehensive, instructive, and valuable, both to those commencing the study of medicine, and to those engaged in the practice of surgery.

Outlines of a Course of Lectures on Military Surgery, delivered in the University of Edinburgh. By SIR GEORGE BALLINGALL, M. D., F.R.S.E., Regius Professor of Military Surgery, &c., &c., 8vo. pp. 589. Edinburgh: 1833. Adam Black.

SURGERY has been greatly improved within a brief period by the writings of the medical officers of the army and navy; and those entering both these branches of the public services possess sources of information which had not existed even twenty years ago. So great was the demand for military

and naval surgeons during the late wars, that young men were sent out as medical officers who were as incompetent as it was possible for them to be. When they commenced duty, they were incapable of performing the simplest operation, venesection excepted; and their incompetence led to the most fatal consequences in numberless cases. After the peace of 1815, the senior surgeons of both army and navy made such representations to the heads of their respective departments, as led to a total change in the education of future military and naval surgeons. The course of education was so much enlarged, that the highest testimonial of competency was required for the subordinate situations in the medical department.

Military and naval surgery was now enriched by the works of Baron Larrey, Dr. Hennen, Mr. Samuel Cooper, Mr. Guthrie, Mr. Hutchinson, and Mr. Hammick, and by various essays contributed by Sir James M'Grigor, Sir William Burnett, Dr. Vetch, Sir Andrew Halliday, Mr. Bacot, Mr. Marshall, Mr. Murray, Mr. Dease, Mr. Lindsay, and many others. These writers communicated a fund of the most useful information, a great part of which was new, as it never had been noticed in the best standard works on surgery. Cooper's *Surgical Dictionary*, Hennen's *Military Surgery*, Guthrie on *Gun-shot Wounds*, and Hutchinson's *Naval Surgery*, deservedly rank as works of authority and reference. In the production before us, the author has analysed the labours of his predecessors,—he has laid all under contribution. He has collected and arranged the whole of the established facts, he has added the result of his own experience, and executed a system of military and naval surgery of inestimable value to those engaged in the practice of that branch of the healing art. But he is by no means sufficiently minute on some essential points; for example, on the selection and examination of recruits for the

army. It is true, he mentions the leading requisites for a good recruit, but he has not described the mode of examination in such a manner as would enable the young surgeon to form a correct opinion of the qualifications required by the army medical board for an unobjectionable soldier. It is very probable that Sir George Ballingall dilates upon this subject in his lectures; but many will read his work who cannot enjoy the advantage of attending his instructions; and therefore we argue the fairness of our criticism. The work on the whole is ably executed, and highly instructive. It will be perused with incalculable advantage by those intended for the army and navy, and ought to have a place beside Hennen's *Military Surgery*.

Some persons assert that there is no difference between civil and military surgery; and this must be granted so far as operations are concerned; but there is a vast deal of important information contained in the latter which is not in the former. In the works on surgery there is no allusion to the examination of recruits, the diet, clothing, and exercise of troops, their accommodation in camp, barracks, and billets, diseases in camps, garrisons, and hospitals, transportation of the sick and wounded, diseases of troops in foreign stations, punishments, feigned and fictitious diseases, medicine chests, surgical instruments, &c., &c. The medical directors of the army and navy boards have therefore very properly recognised one course of military surgery as a part of the course of education of surgeons for the services over which they preside. It is a remarkable fact that there is no professor of military surgery in the numerous medical schools of London or Dublin.

It must be obvious that a work composed of lectures will necessarily contain more lengthened details than an ordinary treatise; and therefore we find much valuable matter in the one which is omitted in the other.

We shall now proceed to make some extracts in proof of this statement. Sir George Ballingall, after having cited the opinions of the best writers on diseases of the army and on military surgery, as to the physical qualifications for a soldier, proceeds as follows:—

“Into the physical defects which ought to lead to the rejection of recruits presented to a medical officer for examination, we can only enter very generally: they could not be easily borne in mind individually, and being specified in the printed instructions furnished to surgeons on this subject, their enumeration here becomes less necessary. My chief object at present is to inculcate the advantages of a systematic mode of proceeding in the examination of recruits. This examination ought never to be entered upon when the recruit is intoxicated, a state in which he is not unfrequently presented to the surgeon. He is, of course, to be stripped naked, and examined generally *a capite ad calcem*, both in front and in rear. He is to be made to move about the room, and to extend his joints and limbs in various directions, which will give the surgeon an opportunity of observing any glaring malformation or distortion of the bones or contractions of the joints. The surgeon is then to proceed more minutely to examine the head, where, if any obvious defect in its general formation, or any marks of severe fracture, with depression, nodes, exostoses, or tinea capitis, are observed, they must be considered as unfitting this individual for the service. All defects in the eye or lachrymal passages, polypi in the nose, malignant tumours in the mouth, extensive deficiency, particularly of the front teeth, any appearance of caries in the jaws, either upper or under, are for the most part sufficient causes of rejection. In the neck, tumours, or rigidity of the muscles, with the marks of previous scrofulous ulcerations, are the circumstances most commonly met with as causes of incapacity. Distortions of the spine, and original malformations, or injuries leading to distortions of the ribs or sternum, so as to affect the circulation or respiration, are decided causes of rejection; as are all indications of a phthisical habit. Abdominal tumours, and hernia protrusions of every description, varicose enlargements of the spermatic vessels, and diseases of the testicles, should be considered as sufficient to incapacitate the individual for the service. Distortions of the arms, thighs, legs, or ankles; exostoses, nodes, ulcers, or extensive cicatrices of ulcers; varicose veins, and contractions or rigidity of the joints, are all to be looked upon as causes of rejection. By adopting this systematic mode of proceeding in succession over the head, trunk, and extremities, much time will be saved; any very serious defect can scarcely escape the surgeon's observation;

and it behoves him, as he values his own credit, the character of his corps, and the interest of his Majesty's service, to be accurate and minute in his inspection.

A duty of equal difficulty and importance devolves upon the military surgeon, in deciding upon the cases of men about to be discharged from the service, particularly of such as are to become a permanent charge to the public as pensioners or annuitants. While, in the examination of recruits, it is the surgeon's duty to see that no man is admitted into the army, who is not in every respect qualified for its duties, it must be equally his care to see that no man is discharged as an invalid, or placed upon the pension list, unless positive and permanent disqualifications exist. Here he must be constantly upon his guard, not only against imposition on the part of the soldier, but he must be prepared to resist the importunities of a commanding officer, an adjutant, or the captain of a troop or company, who are often disposed to load the surgeon with the responsibility of discharging a man who, although possessed of the necessary physical powers, may be troublesome, worthless, or unseemly. Many of the disabilities already enumerated are liable to occur in the common routine of duty, others originate from wounds, and from the vicissitudes of foreign service, to such an extent as to unfit men for the active duties of military life. These disabilities are more particularly specified in the instructions furnished to medical officers, and it seems unnecessary to enter more minutely into the detail of duties which must be in a great measure executed according to the established regulations of the service. The instructions which are from time to time issued to medical officers on the passing of recruits and invalids, in so far as they go, must form an implicit guide; but there are still many points which no regulations or standing orders in this country distinctly provide for. In the writings of Dr. Hennen, of Mr. C. Hutchinson, of Dr. Cheyne, and, above all, of Deputy-Inspector Marshall, much interesting and authentic information is contained applicable to the examination of recruits for the British army, and to the fictitious diseases of soldiers and seamen. Mr. Marshall has made this subject almost exclusively his own; his ‘Hints to Young Medical Officers of the Army on the Examination of Recruits, and respecting the feigned Disabilities of Soldiers,’ and a more recent work on the enlisting, discharging, and pensioning of soldiers, contain a fund of valuable information for which the most experienced will be ready to offer their acknowledgments to the author.

“On many of the points thus cursorily noticed, a medical officer may be greatly assisted in forming an accurate judgment by an attentive study of the French ‘Code de la Conscription,’ of which an abstract is to be found in the sixth volume of the Edinburgh Medical and Surgical Journal. There is also a ‘Me-

moire sur le Choix des Hommes Propres au Service Militaire,' published by Beaupré, an article on the 'Simulation des Maladies,' in the 'Dictionnaire des Sciences Medicales,' by Baron Percy, and some observations on this subject in the 'Hygiene Militaire' of Revolat, well deserving attention. The many attempts made to evade the operation of the conscriptive laws in France during the revolutionary war, induced the authorities to frame and enact a set of regulations for the guidance of those concerned in examining conscripts, embracing almost every point on which a doubt or difference of opinion can exist."—pp. 24—37.

The preceding extract very fully proves the necessity of studying military surgery, because the information it comprises cannot be found in the best books used by students. In the enumeration of works, the author has omitted a great number of French productions, but more especially the *Manuel de Chirurgie Militaire* of Sarlandière which in a condensed form embraces every topic connected with military surgery.

Our limits do not permit us to make other extracts, as it is impossible for a weekly journal to have lengthened reviews, the notice of works being what it professes to give; but the preceding extract affords a good illustration of the manner in which the learned and experienced professor has executed the whole of his work. It is unnecessary for us to state, that we strongly recommend this work to all surgeons who intend to enter the army or navy.

standing the high professional character and reputation of the German physicians who had recorded their experience of its valuable efficacy as a prophylactic, no medical practitioner in France or in this country had yet even given it a trial. He then reported to the Society the favourable views he entertained of it from the experience of his own practice. He conceived the *modus operandi* of the plant to consist in its diminishing, by its narcotic power, the nervous susceptibility of the system, rendering it for a time less capable of receiving the impression of contagion.

Professor A. T. Thomson said, that after the powerful testimony of the German physicians, and the practical experience of the writer of the paper, he could no longer doubt the efficacy of the belladonna as a prophylactic.

Sir David Barry supported the views of Mr. Maclure as to the *modus operandi* of contagion generally, against those thrown out by Professor Thomson, who considered, that in all cases the morbid matter of contagion is absorbed through the skin.

An interesting discussion then ensued; and the general feeling of the members present was, that the subject was one deserving of further attention and investigation, and that experiments of the prophylactic powers of the drug ought to be extensively made.

Monday, October 21st, 1833.

MR. COX in the Chair.

Ioduret of Iron in Chlorosis.

Reports of Societies.

HARVEIAN SOCIETY.

THE third session of this Society commenced on Monday the 7th instant, when Sir David Barry and Mr. Cox, surgeon, were elected Presidents, and a paper was read, by Mr. Maclure, "On the Preservative Virtue of the *Atropa Belladonna* against the Contagion of Scarlet Fever," in which he traced its use, as a prophylactic, from the year 1801 down to the present time. He remarked on the extraordinary circumstance, that, notwith-

A valuable paper was read by Dr. A. T. Thomson, Professor, upon the medicinal qualities of the ioduret of iron, founded upon two cases wherein that substance had been successfully employed. The Professor's remarks tended to show, that the article in question should be used where an increase of vital power, together with increased capillary action, is the main indication, as in extreme and complicated chlorotic cases. An interesting discussion upon the effects of iodine

and its compounds ensued, but, we believe, nothing which has not been previously before the public was elicited. The dose of the ioduret of iron was two grains twice a-day.

Mr. Anderson also communicated an interesting case of obstruction of the vena porta by a substance resembling biliary calculus, attended by hæmorrhage into the alimentary canal, which had several times been arrested by large doses of acetate of lead, but the case ultimately terminated in death.

WESTMINSTER MEDICAL SOCIETY.

Saturday, October 19, 1833,

DR. COPLAND, President.

THE meetings of this Society for the session 1833-34 commenced on the above evening, when the minutes of the last meeting of the former session having been read and confirmed,

Dr. Copland rose to address the members, remarking that the Society commenced its meetings for the ensuing session at an epoch of great moment and interest to every member of the profession, not only as regarded the general interests of the great body of the profession at large, but also as regarded their connexion and intercourse with the public; and that the Committee of this Society thought it right that those questions of medical polity relating to the reform contemplated in the various branches of the profession, as well as in the medical and surgical corporations, should be discussed by the members of the Society, and that the opinions of the Society on these important subjects should be embodied in a petition to the two Houses of Parliament, as had been done in a former session, with reference to the Anatomical Bill. He stated, that in his recent sojourn in the sister kingdom he had found that in proportion as medical practitioners were united, and upheld the just honour and dignity of the profession, so were their professional services valued, esteemed, and proportionately remunerated by the public.

Dr. Webster rose to inquire whether any gentleman present had remarked the prevalence of ague in London within the last six weeks? remarking that he had met with many cases of it recently, occurring in persons who had not been out of London for many years past, and had not, therefore, been exposed to any marshy miasmata, &c. In one case only had he traced the cause of the affection to any miasmata; the most usual form in which he had met with the affection, was the tertian intermittent, and in the treatment he adopted he had found small doses of cinchona, in powder, to arrest the fit and subdue the disease.

Mr. Hunt felt obliged to Dr. Webster for the information he had afforded the society as to the presence of ague in London, and remarked that many practitioners were deceived where they met with a case of ague occurring in London, independent of transmission from any marshy districts or effluvia. An interesting discussion then took place in which Dr. Sigmond, Dr. James Johnson, Mr. Burnet, Dr. Webster, and Mr. Hunt took part, from which, however, no material point of practical importance was elicited.

This being the evening appointed by the rules of the society for the nomination of presidents and members of the committee for the ensuing session,

Dr. Sigmond rose as the organ of the committee, and in an eloquent speech in which he dwelt at some length on the important duties devolving upon the office of president of the society, and on the anxiety of the committee to nominate those gentlemen who in their judgment they considered best fitted to fill such an high and honourable office in the society, proposed Dr. George Gregory and Mr. Gilbert Burnet as presidents for the ensuing session.

A long and somewhat violent discussion here ensued, in which Dr. Johnson, Dr. Gregory, Dr. Epps, Dr. Sigmond, Mr. Hunt, Mr. Costello, Mr. King, and Mr. Chinnock

took part, in the course of which Dr. Gregory begged to decline filling the office of president to the society for the ensuing session, and at the termination of the meeting Dr. Epps, Mr. Hunt, and Mr. Burnet, were, we believe, the gentlemen nominated to fill the office of presidents for the ensuing year, the election to take place at the next meeting (this evening).

Twenty gentlemen were then nominated (ten of whom only are to be chosen), to be on the committee, and Dr. George Gregory gave notice

"That at the next meeting of the society the opinion of the members be taken on the subject of the resignation of the physicians and surgeons of the General Dispensary, Aldersgate-street, with the view of giving the thanks of the society to those gentlemen for their conduct on this occasion, and of expressing at the same time the feeling of this society relative to what virtually amounts to the sale of professional appointments."

THE LATE ALDERSGATE-STREET DISPENSARY. — FURTHER APPROVALS OF THE CONDUCT OF THE LATE MEDICAL OFFICERS.

"Ecce iterum Crispinus."

Jur. Sat. iv. 1.

It is our duty this week, as faithful chroniclers, to place upon the record of our Journal the finale of the Aldersgate-street Dispensary affair.

From the first we anticipated the more than possible result of the obstinacy of the Committee, and of its fatal influence over the best interests of the charity. In the retrospect we can charge ourselves with but one delusion, and, upon consideration, even that appears rather apparent than

real. Up to the last moment of the election farce, no gentlemen of known reputation in the profession offered himself for the invidious office; and, in anticipating such professional conduct, we are proud to say there was no delusion. We had, indeed, dared to hope,—the case was so plain, the motive so honourable,—that no person, by any means belonging to the profession, would have presumed to show the white feather, and desert the ranks to which he had the honour to belong; and that utter helplessness—sheer inability to fill up the vacancies—would have brought the Committee to their senses: therein we were mistaken. The four gentlemen, whose conduct has convicted us of this amiable error, belong to fame. Standing alone, their vanity must have been gratified by an unanimous election. We know not what placebo to administer to their mortification at the chilling disgust they must have already experienced from their professional brethren. Drs. Witsed and Yates are the unenvied and undisputed physicians; Messrs. Caswall and Wyatt the surgeons.

In our last Number we offered a few remarks upon the evils which the wretched system of election, whose results we have just detailed, inflicts upon the medical profession and the poor objects of the charity. There is another evil no less destructive of the permanence of the charity in this same system. The old long-tried friends of an institution, who may have subscribed to its support for many a-year, become disgusted at the venality of such cor-

rupt proceeding, and naturally withdraw their subscriptions; whilst the nominal, elective, subscribers as naturally disappear, when the job is complete. What is the consequence to the charity it is needless to depict. To our own knowledge, there is one institution, not a hundred miles from Sloane-street, under the operation, at this moment, of these natural causes. So monstrous is the mischief against which we have raised our voices in this Aldersgate-street Dispensary affair, that a late Act of Parliament, for the government of the Irish County Infirmaries, abstracted in a recent Number of this Journal, subjects the candidates to a strict scrutiny into their electioneering conduct in creating votes, and exposes the delinquent to a just and condign punishment; the election is annulled, and the convicted party for ever disqualified from filling the office.

We have heard it suggested, that, to meet some of the evils of elections in voluntary charities, the old subscribers should have a number of votes, bearing some proportion to the number of years they have continued to subscribe. In default of a permanent and radical cure for this constitutional taint in most of our public charities,—for which the public in this country is not yet prepared,—we think this idea is deserving of further consideration.

In addition to the testimony of respect and admiration, the late medical officers of the Aldersgate-street Institution have already received from meetings of their brethren at Sheffield,

Nottingham, Cork, and London, we have no doubt, the sentiments of the profession will be as forcibly and unequivocally expressed in their favour, at the meeting of the Westminster Medical Society on Saturday next, when the subject is to be brought under discussion before that body.

We observe, the Committee have again advertised for a candidate in place of Dr. Roberts. No doubt it will find some unknown black sheep to accept the appointment.

TRAVELS OF SIR HENRY HALFORD.

REASONS of State will not allow us, as yet, to gratify our readers with an authentic narrative of the Travels of Sir Henry Halford, to which we alluded in our last. We promise, however, he shall by-and-by, and in due time, be as great a “lion” as Capt. Ross himself on his return from the Polar regions. The worthy Baronet is only “mad nor-nor-west,” but we assure him we too can know “a hawk from a hand-saw.” Before Parliament meets we shall have ample time to prepare for the good fight, which must be fought on the floor of the House of Commons;—we shall be able to give Sir Henry “a breathing.”

MISCELLANIES.

EDINBURGH. — TOWN COUNCIL PROCEEDINGS.—THE COLLEGE. — At the meeting of the council yesterday, a report from the college committee was read, detailing the proceedings of a meeting held with a committee of the senatus academicus, on the subject of the recent increase of the matriculation fee. At this meeting the Lord Provost stated

the grounds upon which the council had resolved to raise this fee; and on the other hand, the committee of the senatus stated the grounds of their objecting to it. The college committee reported as the result of this meeting, that they had heard nothing on the part of the senatus to shake their former opinion as to the propriety of the measure; and that the fears entertained of injury to the university were altogether groundless. The committee recommended to the council to approve of the report, and to remit to Dr. Brunton to prepare a code of regulations for the future management of the college library. The report also recommended that a salary of 50*l.* per annum should be allowed to the secretary appointed by the senatus academicus.

In the course of the discussion on this subject, the Lord Provost observed that the new arrangement would be ultimately in favour of the students, as several small fees had been, and others would soon be, done away with; and the greater facility of access to the library would be highly advantageous to them; since in consequence of the rise of salary given to the sub-librarians, their hours of attendance were increased. In future the library would be open to students from nine o'clock till four (Saturdays excepted) instead of, as at present, from eleven o'clock till two. His lordship also alluded to a negotiation which had been commenced with Professor Jameson, with a view to reducing the price of admission to the College Museum from two shillings and sixpence to one shilling. Mr. Jameson had intimated that this would be agreed to, provided that the Senatus would sanction the change: and the city was in a condition to guarantee that the smaller charge should be as productive as the larger one had been. This his lordship thought the Council could have no difficulty in doing; for, as regarded the sufficiency of the city, he was happy to refer the members of Council to the accounts made up for the last year, from which they would find that

the receipts of the year had exceeded the expenditure by £1700, which must remove all doubt upon that score; while it must also be obvious, that the Senatus could not object with any degree of propriety to any scheme of rendering the Museum more accessible to the public and to the students, to which the Professor of Natural History had given his sanction and approbation; and therefore his Lordship was of opinion, that the Council should not hesitate to confirm their previous resolution, but, by adhering to it, evince their desire to attend to the superior qualities and advantages of the Edinburgh University, which must, in the long run, be a far truer and more sure attraction to students than any petty saving of a few shillings, even although a few of the present professors should continue to exact the small class fees, which most of that body had already agreed to relinquish, and which must, as a matter of course, very soon terminate at any rate.

The report was approved of, and it was remitted to the Lord Provost and the College Committee, to prosecute the negotiation respecting the price of admission to the Museum.—*Edin. Caled. Mercury.*

SCHOOL OF MEDICINE AT NOTTINGHAM.—A school of medicine has just been established at Nottingham, to which the Duke of Newcastle has subscribed £500. If the nobility and gentry in every county were to follow this noble example, every city in England would have its school of medicine and surgery.

Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Severe Compound Fracture.

A MAN, *æt.* 34, was brought into the hospital on October 18, having fallen under the weight of another man while in a state of intoxication, by which the tibia was fractured about its middle. There was an extensive external wound through which the fractured extremity of the bone projected. There was also con-

considerable extravasation of blood. Mr. Earle, under whose care the patient had been placed, deemed it advisable to remove about an inch and a quarter of the bone, with a view to diminish the irritability caused by the projecting portion. The patient is now going on favourably.

Abscess after Gonorrhœa.

Davis, a native of Jamaica, was admitted under Mr. Earle's care with abscess in the anterior part of the perineum, after severe gonorrhœa. There were two fistulous openings at the anterior part of the scrotum, which Mr. Earle enlarged. On further examination it appeared that the patient laboured under contraction of the urethra, at the glans penis. Mr. Earle slit down the orifice of the urethra, since which the patient has improved. Mr. Earle, in his clinical remarks on this case, said that the abscess was caused by the contraction of the urethra, and adduced several instances of similar cases, in which he slit through the contracted part of the penis with the greatest advantage.

Burns.

There are some very interesting cases of burns at present in the hospital under the care of Mr. Earle. There is one very melancholy case of a child (whose history we have given in No. 82 of the Journal), in which adhesions formed between the chin and sternum, as also between the sides of the breast and arm, causing great deformity. Mr. Earle observed that these adhesions were caused by the neglect of those under whose care the child had been, as they would not have taken place if properly attended to. With regard to the adhesions between the chin and sternum, Mr. Earle is adopting a plan which he strongly recommended in his work on burns. In the treatment of those which exist between the arm and breast, he ordered the arm to be extended on a splint, and occasionally bent, so as to preserve the motion of the limb. This treatment has been crowned with complete success in many cases.

ST. GEORGE'S HOSPITAL.

Abnormal Tumour of the Thigh.

John Williams, æt. 58, was admitted on the 11th of September, under the care of Mr. Walker. The history he gave of his case was this:—Five years ago he first perceived a small nodule under the skin at the upper and inner part of the right thigh. It was of a white colour, not painful on pressure, of the size of a pea, and seemingly of the consistence of cartilage. Its size gradually increased, and at the end of a twelvemonth from its first appearance it had attained the size of a small marble, retaining, in other respects, its original

conformation and character. At the end of the third year it was of the size of a pigeon's egg, and during the last twelvemonth it has increased more rapidly in size and bulk, and shooting pains are felt in the thigh whenever the patient uses any active exertion. Six months since it began to change in colour, and became softer in texture, and felt nodulated at its lower part. The pain in the tumour became aggravated, and the paroxysms returned so frequently as to prevent him from following his usual occupation. He has taken no medicine internally, and some simple plaster has been the only external application used.

12th. The tumour was removed. An incision was made on each side, commencing at about one inch and a half above the swelling, and terminating at about one inch and a half below it, thus uniting the two incisions, and including the tumour and an elliptical portion of integument within their circle. The tumour seemed less adherent at its upper than its lower part, where the skin covering it was thin and attenuated. The dissection was continued deeply down, including, with the tumour, a considerable portion of fat, in which it appeared imbedded, and exposing the surface of the adductor longus muscle. No adhesions had been contracted between the tumour and the deeper parts. Four small vessels were secured, the edges of the wound were brought together by sutures, and adhesive plaster, and dressed in the ordinary way.

On dividing the tumour through its centre, a large cavity was found at its lower part, containing from 3iiss to 3iij of a sanguineous coagulating fluid, resembling much in consistence and tenacity the white of an egg discoloured. Internally, the cavity of the tumour was intersected by imperfect septa of thickened adipose membrane or coagulable lymph, dividing it into irregular cells communicating with one another. The upper portion of the tumour, which was solid in structure, appeared to be composed principally of condensed fat, interspersed with various-sized petechial spots, appearing to be in the incipient stage of that disorganisation which was complete at the lower part of the tumour.

The outer surface was unequally nodulated, corresponding in its convexities with the internal concavities in the structure of the tumour. Though previously to the operation the lower portion of the swelling appeared to be closely connected with the attenuated skin, yet it was proved not to be so on dissection.

The wound united readily by the first intention, no untoward symptom worthy of note occurred, and he left the hospital perfectly cured at the end of five weeks.

There can be little doubt, we think, that if the tumour had not been removed it would have degenerated into a malignant disease; and from the complete manner in which the tumour and the surrounding portions of cellular membrane with it were removed, the operation must prove permanently successful.

*Calculus Vesicæ.**(Continued from page 380.)*

Oct. 15. Soon after being bled he rallied in a great measure, and was able to walk from his bed to the water closet; but the paralysis soon returned again.

16. On visiting him this morning we found him decidedly worse, and apparently labouring under all the symptoms of incipient serous apoplexy; pulse 105, and compressible. He had been cupped at the back of the neck; a blister had been also applied; ice had been applied to the scalp, and mustard sinapisms to the calves of the legs and the soles of the feet. Baron Heurteloup, Mr. Brodie, and Dr. Seymour visited him in the course of the day.

5 P.M. Continues much worse; convulsive action of the tarsi; globe of the left eye everted; paralysis of the lower limbs and right arm; has passed his urine involuntarily; pulse as in the morning.

9 P.M. Has not spoken since 4 A.M.; skin covered with a cold clammy perspiration; cheeks cool; moribund; has had an injection administered, which brought away a small quantity of feculent matter.

17. Died at eight A.M.

Autopsy thirty hours after death.—On removing the cranium the cerebrum was found highly injected and suffused with extravasated blood, more particularly the superior, lateral, and posterior portions of the left hemisphere, (the paralysis affected more particularly the right side of the body); the lining membrane of the longitudinal sinus was found slightly inflamed; the lateral ventricles were filled with serum, and there was a rupture of the substance of the base of the posterior portion of the left hemisphere, beneath which there was a large clot of black blood. The coats of the vessels of the brain were found thickened; but the nerves were not noticed as altered in structure or appearance. The contents of the thorax and abdomen were in their normal state; the kidneys were inflamed and softened in their texture, the right more than the left. In the bladder were found many fragments of stone, the largest of which, about the size of a French bean, was the only one which, as Baron Heurteloup remarked, required breaking down to allow of its passing through the urethra: the Baron also remarked that another operation would have completely relieved the patient. The fragments of stone seemed principally composed of lithic acid.

If viewed in all its bearings, this case can scarcely be said to militate against the operation of lithotripsy. The patient had a naturally flushed face, and was of an apoplectic tendency. The only point of treatment against which we are disposed to enter our protest is, that sufficiently active purgatives were not administered to the patient previous to the second operation. His tongue was white, and his bowels were, we believe, confined, and a *lavement* only was administered by the orders of

Baron Heurteloup. We are inclined to think, that had his bowels been kept in a free soluble state the apoplectic symptoms might have been in some measure retarded. The strength and stamina of the constitution, mode of living, diet, &c., are so essentially different in the natives of France and England as to require a disease to be treated on as different principles; and where a gentle *lavement* is all that is required in the one case, the exhibition of an active aperient or cathartic is as imperatively called for in the other.

MIDDLESEX HOSPITAL.

Semeiology, Pathology, and Treatment of Pericarditis.

DURING my attendance at the Middlesex Hospital, I had frequent opportunities of witnessing cases of *pericarditis*, and having perused with much pleasure several valuable papers upon that interesting disease in your excellent Journal, I am induced to make the following observations for the purpose of eliciting more facts from your able correspondents.

The point to which I would first advert is the *existence of a bruit*.—With regard to the value of this sound as a means of detecting the disease, no one who has given common attention to the subject can deny it. I am not prepared to say that "inflammation of the pericardium" must of necessity be accompanied by this phenomenon, but I am strongly inclined to believe that in the generality of cases it is to be found. How is it then that authors—even men of stethoscopic fame, pass over in silence this symptom. I believe, sir, it is because they have not listened early enough in the disease for its detection, and have not examined every square inch of the cardiac region. Be it remembered that this sound comes on very early, almost as it were ushering in the disease. It appears often before any other tangible symptom; and while the careless practitioner reposes in safety, the careful and vigilant is resorting to depletive and anti-inflammatory measures. This symptom however often comes and remains but a short time. It appears suddenly, and as suddenly may depart. It frequently too changes its seat, from being heard nearer the apex, it is discovered only at the base of the heart. And these may afford some reasons why this symptom is so little regarded. I know of no members of the profession who have done any justice to the subject, save Dr. Latham, some years ago, and Dr. Stokes within a later period. These physicians have inquired into the subject with a zeal which is most creditable to them, and with a talent and success which reflects the highest honour upon them as pathologists.

But the most interesting point is the cause of the bruit; whether it be "*bruit de soufflet*," or "*bruit de râpe*." It is, as some authors say, attributable to the increased velocity with

which the blood is propelled. Surely not. A rapid action of the heart may doubtless in some cases, as in hysteria, &c., cause a temporary bruit, but it is dangerous to admit this as the cause in pericarditis, for if we do, we find ourselves in a labyrinth from which it were difficult to extricate ourselves.

Dr. Stokes thinks the bruit depends in many instances upon the friction of two surfaces covered with lymph, and produces cases to bear out this opinion. He says also, which I can from experience corroborate, that the bruit is rapidly removed by antiphlogistic treatment. As to the first opinion, that of friction causing the sound, I am disposed to think it more than probable: we only require an accumulation of facts to establish the theory. I cannot but conceive that the cause of the sound is external to the heart itself: this impression is strengthened by some symptoms of a case at present in the Middlesex hospital. A man with acute rheumatism was placed under the care of Dr. Watson. He was admitted on Tuesday. On Wednesday morning the doctor noticed, for the first time, a puffing sound which attended the heart's action in a space which could be covered by a crown piece, immediately beneath the left mamma. This with other symptoms gave rise to presumptive evidence of pericarditis. The patient was accordingly bled to syncope 3 xviii. The bruit then disappeared. Two hours afterwards it returned, and it was noticed that the action of the heart was singularly altered. *There were three strong impulses given, followed by three contractions with but little impulse; the three former were attended with no bruit, while the latter gave a distinct sawing sound.* The patient became a little flushed, and at the time these symptoms disappeared.

May not this interesting fact be accounted for in the following way.—When the heart contracted forcibly and gave the strong impulse, the obstacle which the lymph afforded was overcome, while when the heart contracted feebly, attrition of the lymph might be supposed to cause those sounds. If this idea be correct, it may be added as an interesting fact to the observations of Dr. Stokes. Upon the present occasion I shall not enter into the affection of the lining membrane of the heart, so frequently a cause of bruit, and so often accompanying acute rheumatism. This no doubt, in a later stage of pericarditis, presents the various morbid sounds so well known to the observant pathologist. Another point, is the position of the patient. Authors tell us that this disease is readily known by the uniformity of its symptoms. This I deny, for many are the cases where no such uniformity has been observed, and many are the autopsies which disclose to the astonished inspector "inflammation of the pericardium," which he least expected. The patient lies on his right side, or his left, or upon his back, instead of being found, (if we trust to books and lec-

tures,) lying immoveably in one position or upon his side. Again, pain in the shoulder, and pain down the arm, must be regarded as very equivocal symptoms. In short, pericarditis often exists without any of the symptoms described by writers. In conclusion, I must enter my protest against the singular contempt with which some medical men, more especially general practitioners, treat auscultation as a means of diagnosis. As a signal instance of this, there are in the Middlesex Hospital at the present time, four cases of chronic pericarditis of an aggravated nature. In each instance the real cause was overlooked in the acute stage, while the effects were combated by depletions to the head in consequence of pain in that part and delirium.

I send you only brief notes of two cases which I have selected out of many. I have chosen fatal cases, the better to exemplify the disease.

FIRST CASE.—*The value of Auscultation—Pathology of acute Pericarditis.*—Robert Scott, æt. 25, admitted under Dr. Watson, April 19th. Acute rheumatism of the knees and wrists of three days' duration; no affection of the chest. He was ordered gr. j. of the ext. of colchicum every four hours. He continued much in the same state till the morning of the 23rd, when upon Mr. Corfe, the apothecary, visiting him, the following note was made in the case book. No sleep during the night, but no delirium. There is a peculiarity in his manner; he is collected, but answers in a strange pert way; an expression of anxiety in the countenance; lying on the left side; pulse 120, undulating; no pain; *pressure in the epigastrium, and in the neighbourhood of the heart does not excite any.* Upon listening to the heart, about an inch to the sternal side of the left nipple, there was a distinct rough sawing sound, not unlike two pebbles being rubbed together.

These symptoms occasioning more than a suspicion of pericarditis, the patient was bled largely, leeches were applied to the chest, and calomel and opium given. "The sound disappeared after the v.s." From this time he continued to get worse; the anxiety increased; there was no dyspnoea, orthopnoea, or pain; the bruit was sometimes distinctly heard, at others but faintly, and not in the same spot. On the 28th he first complained of a catching in the breathing. On the 29th this was much aggravated, and notwithstanding the most active and vigilant treatment, he died upon that day, unaffected by the constant exhibition of mercury. Upon examination the pericardium contained three-fourths of a pint of yellow serum. Its whole surface was covered with reticulated depositions of lymph, thicker in some parts than in others, but no where adherent; some small morbid growths were found about the valves.

SECOND CASE.—*Illustrating the pathology of Chronic Pericarditis.*—Elizabeth Plumb, æt. 17, under Dr. Watson's care Jan. 5th;

acute rheumatism of all the large joints; ill a fortnight; no cardiac affection. This patient was going on well till the 14th, when she complained of cough and pressure at the chest; dyspnoea; and a *bruit* was heard at the junction of the cartilages of the fourth and fifth ribs. She was bled and actively treated, and for a time she recovered apparently, but the *bruit* always existed. She was got under the influence of mercury, but this was of no avail; an idiotic state came on, and she lingered until March 31.

Upon examination there was found enlargement and paleness of the heart. The pericardium was thickened, and so firmly adherent to the heart that it could no where be removed. The valves, as in the former case, were diseased; the morbid growths were large and more extensive.

Epilepsy.—Delirium aggravated by the ingestion of crude Vegetables.

I do not find recorded in books a disease which I suspect is not uncommon, having witnessed several instances; for my present purpose I shall adduce but two, both of which occurred in the Middlesex Hospital.

The disease to which I allude is a perfect loss of consciousness, attended with violent agitation of the whole body, profuse perspiration and delirium, consequent upon crude undigested matter, lurking in the stomach and bowels, thus combining the symptoms of phrenitis, delirium tremens, and chorea in the same disease. To persons who have never witnessed such cases, their features are truly alarming, and would seem to require the most active treatment, while in the following cases the remedies were alike simple and successful.

I am, Sir, yours, &c.

“A PUPIL.”

William Fareweather, *ætat.* 17, under Dr. Hawkins, admitted Jan. 29, 1833. Of a spare habit; face flushed; head hot; violent action of the whole muscular frame, so that when on his legs it requires four men to hold him; talking, hallooing, and spitting about incessantly; does not give rational answers, and will not put out his tongue when desired, but he occasionally, of his own accord, lolls it out of his mouth, when it is seen covered with a viscid mucus. (The symptoms more resemble mania than any other disease.)

He was so outrageous that it was necessary to put on the maniacal jacket. Pulse frequent; not powerful; skin hot; bowels confined. These symptoms have been coming on for some time attended with constipation. (N.B. Has a voracious appetite which has been indulged.) Shave the head and apply cold lotion. Croton oil two drops, immediately.

Vespere. Symptoms aggravated; more wildness in his look; profuse perspiration. Repeat croton oil.

30th. No sleep; bowels not acted on; less strength, but no alleviation of the symptoms. Beef tea *Qj.* daily. Continue the croton oil every eight hours for three doses.

31st. No sleep; the same state; tongue brown; no evacuation. Repeat croton oil.

Feb. 1st. Tongue still brown, and mouth covered with sores; no improvement; has not slept since admission; restraint constantly necessary. To be cupped to *3viij.* at the back of the neck. *Assafœtida* injection.

Vespere. Bowels freely opened; motions offensive, consisting of solid lumps of undigested matter, especially vegetables, as carrots, cabbage stalk, orange rind, potato, &c. Repeat croton oil every morning.

2nd. No sleep; symptoms scarcely relieved; still ungovernably obstinate, refusing to take medicine. Evacuations unaltered.

4th. Decidedly better.

5th. Slept during the night; much better; allowed to be loosened.

He continued the croton oil every morning; and, as the evacuations became more healthy and regular, so the symptoms subsided. He was ordered *sulp. zinc.* one grain three times a day, and the shower bath every morning. Under this treatment he rapidly improved, and after a temporary relapse he was discharged well, March 11. In this case the bowels were evacuated on the fourth day after admission; but it required three more days before the system could recover itself, making it a week before he obtained sleep, and before the strait waistcoat was removed.

John Cox, *æt.* 21, a porter, also under Dr. Hawkins, admitted September 27th. Face flushed, eyes rolling, and the body in constant motion. He is so ungovernable that it is necessary to employ corporeal restraint. He is incessantly talking and singing, and appears not to hear (at least takes no notice) when spoken to. Pulse 120; tongue furred; bowels costive.

His friends state that he has been subject to epilepsy, which had been relieved of late by medicine. He has been permitted to indulge his appetite, and has eaten “whatever he could get hold of.”

Eleven A.M. *Extract. colocynth. gr. x.; Ol. croton. Mj.; stat. et rep. 3is horis.*

Four P.M. No motion. *Enema terebinth. statim.*

Towards evening profuse perspiration came on; agitation not all subdued; lips covered with sores; tongue dry and brown; bowels not open. Still incessantly talking and singing. Head hot and flushed; to be shaved and kept cool.

Hirud. xx. temporibus. Calomel, ʒj. stat. Haust. senna comp. 2dis. horis per noct. donec alv. resp.

28th. There was but little alteration this morning, save that the patient was more exhausted. Restlessness and talking continue,

the latter, however, lower. No sleep; skin hot; pulse quick and full.

Pulv. jalap j. Calomel 3j. statim.

Vespere.—Bowels freely opened five times during the day. Evacuations dark, offensive, and containing undigested apple rind, apple pips, and slimy mucus.

Hyd. submur. gr. iij. 4tis.

29th. Slept well during the night; no evacuation since eight o'clock yesterday evening. He is still singing and talking, but less in degree. He puts out his tongue when told, though consciousness is not perfectly returned. Pulse 90, soft.

Ol. croc. mjj. Ext. coloc. co. gr. xv. fiat pil. iij. stat.

30th. Not quite collected, but perfectly quiet at the time of the visit. Bowels open, evacuations dark, with a quantity of fecal, offensive matter. Slept pretty well. From this time he rapidly regained his consciousness and recovered. The note book states that he had an epileptic fit on the morning of the 4th, and one or two subsequently.

French Medicine.

Treatment of Pneumonia in the Clinical wards of La Charité, by M. Bouillard.

THERE were seventeen cases, all exhibiting the symptoms of the disease in an intense degree. Twelve were bled before the professor saw them, by the *chef de clinique*; in three of whom leeches were simultaneously applied. On the following day, if the constitution were robust, and the pulse still strong and frequent, two bleedings were ordered, one immediately of four *palettes*, the other, not so great, in the evening; and in the interval thirty or forty leeches were applied to the chest where pain existed, and the rattles or other characteristic sounds were heard; or if it were requisite to act with still more energy, two cupping glasses were applied. Seven out of the seventeen were treated according to one of these rules at the first visit. The other ten were bled only once, and had leeches, and, generally, cupping glasses applied. The general bleedings were often repeated for three or four days successively; sometimes there was an interval of a day between

them, and it was rarely necessary to resume them where once dropped.

The application of leeches and cupping-glasses, either together or separately, constantly accompanied by the general bleedings during the first days, and were continued as long as the symptoms were severe. In ten cases blisters were employed towards the end of the disease, when all febrile phenomena had disappeared, and there still remained either more or less pain, some *soufflet* or resonance, uneasy respiration, &c., and it was never found that they brought back the inflammatory symptoms, either local or general. There were also employed with benefit in some cases, at the same period of the disease, poultices moistened with thirty or forty drops of croton oil, which caused much pustular eruption, but never induced fever or over excitement, injurious to the resolution of the disease of the lung.

The objection urged against this mode of treatment is the extreme exhaustion in which the patient is left, and the resulting interminable convalescence. It is a fact, however, that the patients support it easily, and that a few days suffice to restore them to their usual strength. The average period of perfect convalescence was seven or eight days.—*Journ. Hebdom.*

OBITUARY.

DEATH OF CHARLES THACKRAH, ESQ.

Charles Turner Thackrah was born at Leeds, and educated there and in its vicinity. After the completion of his apprenticeship, he went to London and entered as pupil to Guy's Hospital. A prize essay was offered at Guy's on "Diabetes," and Mr. Thackrah was the successful competitor. Soon after commencing practice in Leeds, he obtained the prize offered by Sir A. Cooper to the pupils educated at Guy's Hospital, for the best essay on the blood. This essay was published with additional experiments in verification of his conclusions. Mr. Thackrah was now elevated to a high rank as an experimental physiologist. He delivered at the Leeds Philosophical Institution an extended course of popular lectures on physiology. The substance of these on "Digestion and Diet," was published. His next work, and the one which has gained him more celebrity than all his other productions, was his treatise on the diseases incident to "arts, trades, and professions." The multitude of facts which are embodied in it, and the sound practical conclusions it contains, display great industry, ability, and philanthropy.

Mr. Thackrah's disease was phthisis pulmonalis. He expired on the 23rd of May, 1833. As in the majority of those cases, the delusion existed, that he would recover. "Bronchitis (he said) is my chief malady."

A complete analysis of Mr. Thackrah's intellectual character would occupy many pages. It would display the workings of a cultivated and energetic mind, spurred on by ambition, encountering difficulties, and surmounting obstacles, which few could have accomplished. The death of such a man is to be deplored as a public calamity, and not merely as affecting relatives and friends.

Mr. Thackrah was not, in the common acceptance of the phrase, a man of genius, but he had qualities possessed by few. Industry to collect facts; honesty to narrate them with fidelity, judgment to generalise them; perseverance to pursue an inquiry; and he had ambition and the love of approbation to impel him to exertion. Nay! he was a slave to popular applause.

The Sanctum.

Sedative Effects of the White Ash on the Rattle-Snake.—The following curious facts are from a letter of Judge Samuel Woodroff to Professor Silliman, in the last number of the *American Journal of Science*:—

"Some time in the month of August, I went with Mr. Kirtland and Mr. C. Dutton, then residing at Portland, to the Mahoning for the purpose of shooting deer. About an hour after we commenced our watch, instead

of a deer, we discovered a rattle snake, which, it appeared, had left his den in the rocks beneath us, and was advancing across a smooth, narrow sand beach towards the water. It occurred to me that an opportunity now offered to try the virtue of the white ash leaves. Requesting the gentleman to keep, in my absence, a watch over our object, I went immediately in search of the leaves, and on a piece of low ground, thirty or forty yards back from the river, I soon found, and by the aid of my hunting knife, procured a small ash sapling, eight or ten feet in length; and with a view to make the experiment more satisfactory, I cut another sapling of the sugar maple, and with these wands returned to the scene of action. In order to cut off the retreat to his den, I approached the snake in his rear. As soon as I came within seven or eight feet of him, he quickly threw his body into a coil, elevated his head eight or ten inches, and, brandishing his tongue, 'gave note of preparation' for combat.

"I first presented him with the white ash, placing the leaves upon his body. He instantly dropped his head to the ground, unfolded his coil, rolled over upon his back, writhed and twisted his whole body into every form but that of a coil, and appeared to be in great anguish. Satisfied with the trial thus made, I laid by the white ash. The rattle-snake immediately righted, and placed himself in the same menacing attitude as before described. I now presented the sugar maple. He lanced in a moment, striking his head into a tuft of the leaves, 'with all the malice of the under fiends,' and the next moment coiled and lanced again, darting his whole length at each effort with the swiftness of an arrow. After presenting this several times, I again changed his fare, and offered him the white ash. He immediately doused his perk, stretched himself on his back in the same manner as at the first application. It was then proposed to try what effect might be produced upon his temper and courage by a little flogging with the white ash. This was administered; but instead of arousing him to resentment, it served only to increase his troubles. As the flogging grew more severe, the snake frequently struck his head into the sand as far as he could thrust it, seeming desirous to bore his way into the earth and rid himself of his unwelcome visitors.

"Being now convinced that the experiment was a satisfactory one, and fairly conducted on both sides, we deemed it unnecessary to take his life, after he had contributed so much to gratify our curiosity; and so we took leave of the rattle-snake, with feelings as friendly at least as those with which we commenced our acquaintance with him, and left him to return at leisure to his den."

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXI., DELIVERED MARCH 1, 1833.

GENTLEMEN,—There are two or three preparations on the table illustrating the subjects which I was considering in the lecture delivered yesterday evening. That which I now send round exhibits the appearances of the periosteum in an inflamed state. The portion of skull, which I will next pass to you, shows the appearances, produced by the kind of caries called *worm-eaten*, occasionally noticed in the worst stages of syphilis. I have seen some specimens, however, in other museums in London, which show its characters still better than this preparation before us; but it will convey to you an idea of the nature of this remarkable form of caries. You see that the bone is perforated in numerous places, and in various directions, giving it an appearance as if the mischief had been really produced by the process to which the term "*worm-eaten*" refers. These bones show the appearances arising from the venereal caries of the tibia; in fact, they are specimens of nodes, combined with caries.

Now, gentlemen, the next subject requiring your particular attention is *necrosis*, or the death of a portion of bone, sometimes of the greater part of it; for, not unfrequently, you will see the whole of the shaft of one of the long cylindrical bones destroyed. Here is a preparation, exhibiting a complete osseous case, formed as a substitute for the whole shaft of the tibia, which has been destroyed, or, as we say, which is in the state of necrosis. It is a beautiful specimen. The term *necrosis*, according to its etymology, has nearly the same signification as *mortification*; but, by the general consent of surgeons, it is now employed exclusively to signify the death of bone.

VOL. IV.

I told you, in the last lecture, that between *necrosis* and *caries* of the bones, as much difference exists as between *mortification* and *ulceration* of the soft parts. In *caries*, the function of nutrition in the bone is considerably disturbed and impeded; portions of the osseous substance are removed; but what remains is still alive. On the other hand, in *necrosis*, the part is entirely dead, its vital functions have completely ceased, and there is no longer any circulation through it. As I have explained, the mischief of necrosis may extend not only to a small portion of bone, but sometimes to the whole shaft of one of the long cylindrical bones. Generally, however, the head of the bone escapes; the articular parts are usually spared; and, when the new shaft is formed, the original portions left, which are commonly the ends of the bone, become grafted, as it were, on the new osseous case.

After a portion of a bone has perished, or fallen into the condition of necrosis, its detachment and removal become as necessary, for the process of reparation and the cure of the patient, as the taking away of any other extraneous substance lodged in any part of our frame, and keeping up irritation, suppuration, and other effects; indeed, the dead bone is to be now regarded as an extraneous substance, and its removal from the part, either by the action of the absorbents, or by surgical proceedings, is absolutely necessary. It matters not, as far as the nature of the disease is concerned, whether merely one layer of the bone is affected with necrosis, or the whole substance of it—the disease is still essentially of the same kind; and the various circumstances of depth and extent, to which the disease may have proceeded, relate only to its severity, and certainly are of great importance as far as regards the prognosis, the prospect of cure, and the length of time which will necessarily elapse before this desirable event can be accomplished; but the disease is *necrosis*, whether a small portion of bone perishes, or the whole or greater part of a bone.

While *caries* mostly affects the spongy parts of bones, and those bones which are of a light texture, *necrosis* is found to attack principally the harder parts of bones, and those bones

EE

which naturally contain the greatest quantity of phosphate of lime, and are of a firm compact texture; and this is so much the case, that those circumstances which would produce necrosis in the harder parts of bones, seem mostly to cause caries when they exert their operation on the softer spongy parts of the skeleton. Among the bones most frequently attacked by necrosis, I may mention, first, the tibia, then the femur, the lower jaw, the clavicle, the radius, and the ulna. The bones of the cranium are also frequently the seat of necrosis. Of all the bones of the skeleton, I believe none so frequently suffers from necrosis as the tibia. The disease now engaging your attention is one to which both sexes are liable, and this at any period of life; yet we find, that the disease is more common in very young persons, and especially in those who have scrofulous constitutions, than in other individuals. But this observation must be received with one qualification, namely, that all persons who are exposed to dangerous and laborious employments, whose pursuits render them liable to suffer from accidental external violence, are frequently the subjects of necrosis, and this, whatever may be their age or the nature of their constitution.

Gentlemen, although the most extensive forms, or degrees, of necrosis are chiefly seen in the long cylindrical bones, we do also sometimes meet with them in the flat ones; and even the short thick bones are occasionally quite destroyed. I have, indeed, already explained, that the bones of the cranium are not unfrequently the seat of the disease, and that the lower jaw is very often affected. You will find also in the records of surgery many instances, in which the scapula was attacked. One interesting fact, relating to this subject, I mentioned in the beginning of this lecture, which is, that when the shaft of a bone has perished, or fallen into the state of necrosis, its heads, or articular extremities, almost always continue to live; and afterwards, a process is established, by which they are united to the new osseous formation, covering the dead shaft. The examples to the contrary, though possible, are very rare. You may observe, that, in this preparation, the heads of the original bone are still preserved. In another preparation, which is on the table, and which is the femur, you may notice, that though the head of the bone has been immensely inflamed, and is rendered quite misshapen, yet it has not been destroyed; it is the original extremity of the bone that remains; and, although it has suffered severely from inflammation, this has produced no other effect on it, than that of making its surface exceedingly rough and irregular. What new bone presents itself, you see, has been thrown out below the articular part. Cases do sometimes happen, but they are very uncommon ones, in which the articular parts of bones are destroyed, or involved in the mischief of necrosis; and, then, as the shaft is more or less destroyed at the same

time, the prognosis is generally unfavourable, and amputation of the limb can scarcely be avoided.

Gentlemen, with respect to the *causes of necrosis*, I may inform you, that every thing, affecting the periosteum, the substance of the bone, or the medulla in such a way as to interrupt the nutrition of the bone, may conduce to the origin of necrosis. The causes, therefore, of necrosis may be divided into external and internal ones, the external causes are principally severe contusions, bad compound fractures, the pressure and irritation of foreign bodies in the substance of the bone itself or in its cancellous structure, (the lodgment of a musket ball there, for example, may produce necrosis), the long-continued exposure of the surface of a bone deprived of its periosteum to the air will lead to necrosis of the portion which is so exposed; and irritating the surface of a bone with acid or caustic applications will produce a similar effect. Thus sometimes the free use of strong concentrated acids in the treatment of sloughing ulcers on the shin will, if care be not taken, produce necrosis of the tibia. You may remember, that I showed you, a few evenings ago, a specimen of part of the cranium, which had been attacked by necrosis in consequence of a burn.

Whenever the old surgeons saw a portion of bone exposed to the atmosphere, and deprived of its periosteum, they concluded, that a cure was impossible without exfoliation of the part of the bone thus uncovered; they fancied that it would of necessity become attacked with necrosis, and thrown off from the living part of the bone before a cure could be accomplished. But, gentlemen, this was taking an erroneous view of things; it does not follow, that a bone must die and exfoliate under the circumstances I have mentioned. It is true, that, if the bone has suffered much contusion, if the patient is old, feeble, and unhealthy, and, especially, if the exposure has been long continued, necrosis will most probably take place. But, former practitioners were confirmed in their erroneous opinion by invariably committing two errors in the treatment of these cases; in the first place they did not take care to cover the exposed portion of bone, as quickly as possible with the soft parts, which had been detached from them, and thrown back in the form of a flap; and, in the second place, they commonly dressed the wound with irritating applications, and with what they conceived was calculated to promote exfoliation. Such practice would of course tend to confirm the view which they had taken of the case; for, under the kind of treatment referred to, necrosis would be pretty certain to follow; whereas, if they had promptly covered the exposed bone, with the soft parts, and had then resorted to proper dressings, they would soon have discovered that the simple exposure of the surface of a bone is not necessarily followed by necrosis; and that exfoliation is not always to be apprehended as a matter of certainty. We know,

that the osseous texture does not depend entirely on the arteries of the periosteum for its nutrition; and that those of the medullary membrane are materially concerned in this function; hence, it does not follow, that a bone must perish, because it is deprived of its periosteum. On the contrary, if the patient be young and his constitution sound, if the bone be not too much contused, and not kept exposed too long to the atmosphere, or dressed with improper drying, astringent, spirituous applications, the production of necrosis may generally be avoided. All this implies, however, that the violence which has given rise to the accident, has not operated too much on the medullary texture. When a limb has suffered such a degree of injury, that the periosteum is detached from the surface of the bone, along with the soft parts, an injudicious method of proceeding will of course bring on necrosis of the exposed bone; but, if the loosened flap of soft parts be immediately laid down again; and no stimulant applications be used, you may have no necrosis at all, and, of course, no exfoliation; granulations will spring up from the surface of the bone; these will unite to those arising from the soft parts, and a complete cure will often follow with extraordinary expedition, particularly in young and healthy subjects.

But, gentlemen, necrosis, and the worst forms of it, may proceed from internal causes, that is to say, from causes which affect the bone, through the medium of the constitution. Experience proves, that necrosis may follow that deranged and debilitated state of the constitution, which is left after various kinds of febrile disturbance. The origin of some of the worst cases of necrosis may be attributed to the debilitating effects of typhus fever, small-pox, or even measles. Scrofula, lues venerea, scurvy, and the prejudicial influence of a badly conducted course of mercury, have all been known, under particular circumstances, to excite necrosis. When mercury gives rise to this affection, it is generally when that medicine is administered for the cure of syphilis, and the patient does not, during such mercurial course, take proper care of himself, being exposed to the vicissitudes of the weather, or incautious in his diet. In many instances, the mischief is brought on by the mercury being given in excess, or by small quantities acting with unusual violence. The bones, which most frequently suffer under these circumstances, are the lower jaw, and part of the alveolar processes of the upper jaw, more frequently the latter. A few days ago, I saw a woman, who was attacked with a most severe salivation, though she had only taken seven or eight grains of blue pill; most of her teeth dropped out; and the jaw was partly in the state of necrosis: her life is now in the utmost danger.

The old surgeons used to imagine, that pus had a corrosive quality, and that, when it was left in contact with a bone, it would destroy a portion of it, but this doctrine is now exploded.

It is true, we frequently find necrosis and abscesses combined together; we sometimes find matter on the surface of a bone, part of which has perished, but the latter circumstance is usually in consequence of the very inflammation, which gave rise to the abscess, having extended its effects to the bone itself; the bone, therefore, suffers from the same causes as produced the suppuration. It is, however, possible to conceive that an abscess may produce necrosis, when its pressure operates upon the bone in an extraordinary degree; then, indeed, it is possible, that necrosis may be occasioned by an abscess, but certainly not by the supposed corrosive qualities of pus; the principle is a very different one. In many instances, where necrosis is combined with suppuration, the matter has not been in contact with the bone at all, the periosteum intervening between its surface and the abscess; in such a case, it is impossible even to suspect that the necrosis can have been produced by the corrosive quality of the purulent matter.

Now, gentlemen, I will devote the remainder of our time this evening to examinations on the important subject of aneurism, through which we have lately proceeded. The consideration of necrosis, I will resume at the next lecture.

CLINICAL LECTURES

DELIVERED BY

DR. WILLIAM STOKES,

At the Meath Hospital, or County of Dublin Infirmary, Session 1832-33.

LECTURE XVI.

Fever, and the Theory of Broussais.

GENTLEMEN,—In my last lecture I commenced the examination of the system of Broussais, and drew your attention to several leading principles connected with that very remarkable doctrine. I noticed in the first instance, that the author has termed it the physiological doctrine, and stated, that what he means by this is, that, in his system, he endeavours to explain the nature and cause of disease as not arising from any new condition of the economy, but as the result of a plus or minus degree of vitality, affecting not the whole but particular parts of the body. His idea of inflammation is, then, that it is a plus state of the natural action of the parts, or, in other words, that it is an elevation of the vitality of part of the body. For instance, if we examine a serous membrane in a state of health, we find that its vitality is low; it possesses but little sensibility; it is pale, bloodless, and without red vessels; it represents the imperfect animalisation of a white blooded animal. But let this same membrane become the seat of inflammation, and you will perceive in it a rapid development of vital energies; it becomes exceedingly painful;—there is an increase of sensibility;—its vessels, which before only

E E 2

carried white blood, now transmit red; this is another example of increased vitality. In health it secretes only a fluid, containing but a small portion of animal matter; in disease this secretion is altered, and the serous membrane eliminates a highly animalised product, lymph is shed over its surface, and this lymph quickly assumes the characters of an organised texture. So that when we look at a serous membrane, in a state of inflammation, we observe, in the first place, an increase of sensibility; next, the presence of blood in its vessels; thirdly, a secretion of a higher degree of animalisation; and, lastly, a power of new organisation. Diseased action, then, according to the opinions of Broussais, is not new to the economy, it simply consists in a plus or minus degree of vitality occurring in any organ or system of the body. A remarkable work has lately been published by the celebrated anatomist Serres, in which he attempts to prove that there is nothing in diseased action foreign to the economy, and he puts this forward as a discovery of his own, although an opinion exactly similar had been previously advanced by the physiological school.

I have before mentioned, that Broussais, struck with the similarity in essence of most diseases, rejected altogether the doctrine of specific inflammations, but that, in doing so, he had gone too far, and totally failed in establishing his position. I also drew your attention to one of the fundamental principles of his system, the localisation of disease, and showed that his exclusive solidism was one of his most fatal errors. The arguments which would express my views on this subject are as follows:—As the chemical composition, anatomical character, and physical disposition of the fluids and solids are analogous; as there is no exact line of demarcation between them, and as (without asserting the vitality of the fluids) there is every reason to believe, that they are under the influence of the nervous system, there is no reason why, if disease begin in any part of the solids, it cannot also begin in the fluids, and if so, then we may have diseases not primitively local. Unless Broussais can establish a distinct line of difference between the fluids and solids, and prove that the former are independent of the nervous system, he will not be able to disprove the opinion, that disease may commence in the fluids.

You will recollect, gentlemen, the distinction which I made between the theories of Brown and Broussais, as it is of importance in entering on the subject of the theory of fever. Brown applied the terms *sthenia* and *asthenia* to the economy at large; Broussais to the organs in particular. With Broussais one part of the body may be in the state of *sthenia*, another in that of *asthenia*; this Brown did not conceive. One of Broussais's propositions was, that where we have inflammation, or *sthenia*, of a particular organ, it implies *asthenia* of some other part; of this Brown had no idea, for he considers that all the organs are

at the same time in a state of *sthenia* or *asthenia*. Now, although I think Broussais has failed in establishing, as an universal law, the original local origin of diseases, yet there can be no doubt, that *he has shown that a great many affections, supposed to be essential and independent of any particular local lesion, in reality arise from disease of some particular part of the body.* There is one point connected with the theory of Broussais, to which I would draw your attention at present; it seems to afford some explanation of some remarkable facts in medicine, which have often surprised practitioners, I allude to the power of the economy in bearing enormous doses of medicine in many forms of diseases, which could never be borne in a state of health. In cholera and tetanus patients will take hundreds of grains of calomel without being salivated. Now, Broussais explains this by saying, that, in tetanus, we have a *sthenic* condition of the spinal centre, and in consequence of this an *asthenic* condition of the abdominal viscera, which are thereby rendered insensible to the stimulus of the mercury and remain unaffected.

You, perhaps, remember a very remarkable case of low peritonitis in this hospital, in which one hundred and twenty grains of opium were given in the space of a few days without producing narcotism. In the same way the tolerance of tartar emetic in acute pneumonia has been explained. In a state of health, and where there is an equilibrium of vitality, a small quantity vomits, and if continued is likely to produce inflammation of the stomach; but, in a case of violent pulmonic inflammation, we may give ten, twenty, or even thirty grains of tartar emetic in the day without the hazard of superinducing gastritis. Why is this?—Because the stomach can bear a stimulus which in a state of health would prove pernicious. There are certain circumstances in favour of this opinion. The more violent an attack of pneumonia is, the greater is the tolerance of tartar emetic, and we find that as the pneumonia declines the tolerance declines also. In the next place, the cases in which the tolerance is greater are those in which there is no inflammatory condition of the stomach. Other examples of the same kind may be cited, but it is a question whether these facts are always to be explained by the law of Broussais, or whether other conditions of the system, besides the *sthenia* of a particular organ, are not necessary for their occurrence.

Although Broussais has failed to establish, as an universal law, that the origin of all diseases is local lesion, yet there can be no doubt that he has contributed much to the improvement of practical medicine, by showing that many affections, supposed to be essential, depend upon the lesions of particular organs. It is a singular fact, that in this opinion he is strongly borne out by two very celebrated British pathologists, Dr. Parry and Mr. Abernethy. According to M. Broussais, we have local disease giving rise to two classes of

symptoms; first, the phenomena of the suffering organ itself; secondly, the phenomena proceeding from the sympathies of other parts with the organ originally affected. Both classes are observed in many cases of local disease. It is in those cases particularly where the second class of symptoms are predominant, that the disease has been supposed to be essential; and in demonstrating the local origin of many of those diseases, and thereby pointing out the true principles of treatment, Broussais has earned a crown of laurels of which his own errors can never despoil him. Take a few examples of this. Suppose a man gets an attack of gastro-enteritis. Here we may observe two classes of symptoms; first, the abdominal tenderness, pain, tension, and derangement of secretion, which are characteristic of local disease. But we have frequently another train of symptoms: we have all the phenomena of typhus fever, prostration of strength, delirium, coma, hurried breathing, cough, and quick pulse. Now in those cases where the second class of symptoms are predominant, the preceding local mischief is frequently overlooked, and the disease is supposed to be essential, and maltreated accordingly, although its phenomena are only symptomatic of an original local affection. It is in separating what is secondary and symptomatic from what is original and primitive, that the great improvement has been made. Another interesting example of an affection supposed to be constitutional is seen in the pathology of hectic fever. Hectic was formerly thought to be a nervous affection, a constitutional disease, an obstruction of the fluids,—in fact, any thing but the result of local disease. But it is now known to depend on local irritation, that its severity is proportional, and that we can modify or even remove it by applying our remedial means to the local mischief. The opinion still commonly taught in schools is, that hectic fever is produced by the absorption of pus into the system, and that the sweats which attend it are imperfect attempts at crisis. Without denying that purulent absorption may cause it, we find that it may exist in cases of chronic inflammation where there is no pus absorbed into the system. We observe hectic without suppuration, and we have cases of profuse suppuration without hectic. When lecturing on the subject of phthisis, I drew your attention to this fact, and stated that the violence of the hectic fever is in proportion to the irritation and extent of the pulmonary disease, and not to the suppuration.

Two of the most important results of the theory which upholds the localisation of disease are, first, the doctrine of revulsion, secondly, that of sympathy, to the consideration of which I would earnestly draw your attention. On these all-important subjects I may safely say that, for the greatest part of our knowledge we are indebted to Broussais. Revulsion, or derivation, is a term frequently

heard among medical men, but perhaps not generally understood. With the older authors revulsion and derivation were significant of different ideas; at the present time the same meaning is attached to both. The term revulsion is used in a two-fold sense; first, as indicative of a modification produced by art; secondly, as signifying a modification occurring independent of any artificial means. What is this modification?—A change of the seat of disease. Let us take examples of each:—Suppose you have a patient labouring under a chronic inflammation of the lungs;—well, you apply a blister over the chest, inflammation of the skin comes on, and the chest disease subsides. This is an example of artificial revulsion; a new disease is produced, and as a consequence of this the original one subsides. Now take an example of natural revulsion:—A patient has disease of the lung, cough, pain in the chest, and hurried breathing; he gets enteritis, and the pulmonary affection disappears. Or, a person labouring under an affection of the head, with coma and delirium, gets erysipelas, and, according as the disease of the skin comes on, the cerebral disturbance subsides. You perceive, therefore, that the theory of the localisation of disease is necessary for the doctrine of revulsion; for if the whole system was affected, we could not have a change from a diseased to a healthy part. Besides, it is a fact, that if we look to those diseases in which there is an universal morbid condition as in scurvy, and other diseases, we find that the revulsive plan is not so applicable, or natural revulsion observable. We only find revulsion useful, where there is a predominance of irritation in particular organs.

From an examination of the relative importance of different organs to life, and the power they possess of relieving themselves from disease, Broussais has brought forward several curious and important laws. You remember that when lecturing on the subject of arthritis, I spoke of three kinds of revulsion; first, the change of disease from one viscus to another, or internal revulsion; secondly, revulsion from external to internal parts, or central revulsion; and lastly, from the viscera to the surface, which may be termed peripheral revulsion. Let us take examples of each of these forms:—A patient has gastritis, and this subsides on the supervention of pneumonia, or bronchitis, and this disappears by a diarrhoea coming on. This is an example of the first kind, or of the change from one viscus to another. An example of the second species of revulsion consists in the subsidence of an attack of erysipelas of the scalp when inflammation of the brain appears; here is a change from external to internal parts. Lastly, the peripheral revulsion, or a change from the viscera to the surface, is a circumstance which may be observed every day in the cold fit of ague, and is that form which is most frequently employed in the practice of medicine. With respect to the value of these different modes,

you will recollect that I have spoken at large in a former lecture, and shown that the visceral revulsion is a mode of which the utility and safety may be questioned except under particular circumstances. There are two cases in which it may be employed with advantage; first from a more to a less essential organ; secondly, when the revulsion is from an organ which cannot easily relieve itself by secretion to one which can. Thus suppose we have an inflammation of the brain, here is an organ which cannot relieve itself by secretion, but by a revulsion to the bronchial or gastric mucous membrane we have a change to an organ capable of relieving itself. With respect to central revulsion, or the change from external to internal parts, this is a mode which is always dangerous, because it implies a change of disease from a tissue, the healthy action of which is not so important to life, to one which is highly essential. It appears, therefore, that of all those forms, the least dangerous and most useful is that in which the disease is transferred from internal parts to the surface of the body. Thus, let a person who is affected with any internal disease get erysipelas or any other cutaneous affection, and you will often observe a subsidence of the original complaint.

From observing the extraordinary cures effected by the aid of revulsion medical men have been borne away too much by an attachment to this mode of treatment, and, in fact, if we consider the practice of medicine as it is carried on in these countries, we shall see that the great proportion of it consists in revulsive means. For instance, the attempt to cure visceral disease by exciting diaphoresis is a revulsion; to endeavour to remove a pneumonia or an enteritis by diaphoretic medicines, is only to endeavour to relieve the viscera by determining to the surface. In the same light are we to look upon the practice of attempting to remove or relieve chronic disease of the liver by purgatives. Certain affections of the head, characterised by acute pain, we try to remove by purgatives and stimulants, as nitrate of silver; here again revulsion appears. Almost all those anomalous affections which occur among females, and are attributed to derangements of the uterine system are treated by stimulants applied to the stomach and intestinal tube. The great error is that in doing all this we think we are able to imitate the processes of nature exactly. But we are not capable of following these nice and subtle operations, and though we may produce irritation or excitation of another tissue, still it is against chances to suppose that we can combine all the elements for a successful result. Broussais carefully points out what practitioners in general never seem to dream of, namely, that all revulsives are stimulants. It may be said, as in the case of purgatives, that they are only local stimulants. True, but in many instances they are general stimulants, and in almost all instances, if long continued, they will have a general stimulant effect. In this case they

will ultimately excite disease of the organ to which they are applied, and through its influence the system at large; so that what was at first local, becomes afterwards general. In fact when we consider the revulsive treatment in inflammatory diseases, we can scarcely call it antiphlogistic, it is in reality stimulant, and all that is effected by it is to change the inflammatory action from one part to another. There is nothing directly antiphlogistic in it, all revulsives are stimulants, and of this I believe practitioners are not sufficiently aware. There is another very important circumstance. If the organ to which the revulsive treatment is directed does not quickly relieve itself by secretion, it may become more inflamed. If we employ diuretic medicines in the treatment of disease and fail in exciting the action of the kidneys, these organs may take on the inflammatory condition. In the same way in administering drastic purgatives we may not be able to produce intestinal secretion, and enteritis is the consequence. Suppose you have an affection of the liver to deal with, and you attempt to relieve it by purgation, this is only revulsion, if the purgatives do not succeed, and if a free secretion from the intestines does not take place, you will not be able to alleviate the liver disease, on the contrary you will only add to it by superinducing enteritis.

For the advantageous action of revulsive medicine two conditions seem necessary; 1st. That it shall excite the organ to such degree only that its action will not be reflected on the system so as to produce febrile disturbance. 2nd. That it shall not disorganise the part by over excitement. In fact the revulsive is a dangerous mode of treatment, and the scientific and cautious practitioner will not employ it when he can dispense with its services, and use some safer therapeutic means. Unfortunately medicine is not sufficiently advanced in other modes of treatment to be able to reject the revulsive plan, but medical men should always recollect that revulsives are not direct antiphlogistics.

We come now, gentlemen, to the consideration of the laws of sympathy. When we consider the system in a state of health, we find that the effects of impressions made upon one organ are rapidly transmitted to others. We observe, too, that excitement of one organ produces excitement in another and a distant one. These are the sympathies of health; and the organs of their transmission are supposed to be the nerves. Now, in disease we see the same phenomena; and Broussais maintains, that the morbid sympathies only differ from the healthy in this—that they transmit more irritation, or, to use his own words, a mode of excitation repugnant to the vital laws. It is plain, that if by the latter expression he means anything more than a plus degree of the natural excitement, he is departing from the principles of his doctrine.

Broussais divides the sympathies into two classes,—sympathies of relation, and sympha-

ties of organic life. What does he mean by this? Modern physiologists have divided the functions into two classes,—those of animal and those of organic life. The centre of organic life is the great sympathetic nerve; the central organ of animal life is the brain and spinal cord. To give an example of sympathies, let us take a case of inflammation of the mucous membrane of the intestinal tube. During the course of the disease the patient gets headach—here is a sympathy of relation; next, we observe convulsions—here is another effect of sympathy; he becomes delirious—another similar result of the same cause; and all these are sympathies of relation. Let us go further. The same patient, as the result of an enteritic attack, gets fever, heat of skin, excitement of the circulation, and jaundice—all these are organic sympathies. Again; during the course of the same disease the patient may get an attack of cough and a difficulty of breathing—here is another organic sympathy, for the respiratory organs are affected. When the sympathies of relation are in excess, the results of that excess may vary according as they are reflected on the nervous system; and if these be very violent, the person may die of the excitement of the organ of animal life. If the sympathies of organic life happen to be excessive, the patient may be destroyed by the transmission of disease to other viscera: he may die of disease of the lungs or liver, or some other organ. This may tend, in some degree, to explain the laws of sympathy. On this subject Broussais has announced propositions too numerous to be laid before you in the course of a few lectures. To one of them, however, I would particularly draw your attention, namely, that sympathetic functional derangement when excessive and long continued may ultimately become real, or, in other words, that the affection of an organ, when persistent, may, though at first functional, afterwards become organic. Take the example before given, of a patient labouring under enteritis, with severe headach. If the disease continues for a long time the brain may become inflamed, and the patient die of cerebral disease. Two conditions, therefore, may produce the conversion of sympathetic irritation into real disease, intensity of symptoms and long continuance.

Let us take a few examples of the first class of diseases, or those which arise from an intensity of sympathy. A patient gets an attack of hepatitis, or pneumonia, or bronchitis; the action of the heart is disturbed or excited, the disease continues with undiminished intensity, and the heart, which was originally only affected by sympathy, finally experiences an organic change. Again; a person is seized with severe gastro-enteritis; during the progress of the disease his breathing becomes hurried, he gets cough and other symptoms of a pulmonary affection, and finally, intense and fatal pneumonia. A child labours under irri-

tation of the brain; this produces vomiting, and the vomiting may ultimately terminate in gastritis. On the other hand, we may have hydrocephalus supervening on an intense gastritis. Again; to take instances of disease arising from sympathy, with chronic and long-continued affections, how often do we read of persons, having constant headach from chronic gastritis, finally dying of disease of the brain. In the same way a gastritis may, in course of time, bring on hepatitis, or perhaps disease of the lung, forming what has been termed *dyspeptic phthisis*. How frequently is morbus cordis the result of long-continued pulmonary affections. Does not long-continued painful menstruation frequently end in organic disease of the uterus? These are examples of persistent sympathetic irritation terminating in organic disease, and tending to establish the great rule, that long-continued functional lesion is closely connected with that process which produces organic change. *It is, therefore, unscientific and dangerous to prescribe, on all occasions, for a chronic functional affection, on the supposition that it is only such; it is often safer to consider it as a disease of the organ itself.* Let us see how this is borne out by facts. It is now admitted by the most enlightened pathologists, that in cases of mania which have been going on for years, there is always more or less of arachnitis, or of disease of the substance of the brain, and that the patients die with symptoms of a cerebral affection—as convulsions, paralysis or coma. Let a patient labour for a considerable space of time under severe palpitations, and the result may ultimately be disease of the heart; or let him be dyspeptic or asthmatic, and he will commonly get a gastritis or organic disease of the lung.

I intended to have entered on the subject of inflammation, and to have examined the opinions of Broussais on this all-engrossing topic, but, as I perceive my time is nearly expired, I must defer it until our next meeting. I shall then draw your attention to what he has effected, in showing the vast extent of local inflammatory action, and the error he has fallen into in his theory of inflammation. Yet, if he had done nothing more than to demonstrate the inflammatory nature of some diseases not previously known to be such, and thereby succeeded in discovering the true key to their prevention and treatment, it would justly entitle him, in my opinion, to rank as one of the first physicians of the age.

LECTURES
ON THE
PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,
BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE IX.

Duties of the Obstetrician at the Birth of the Infant.—Section and Ligature of the Funis umbilicalis, or Navel Cord.—Ablution—Dress and Management of the new born Infant.

GENTLEMEN,—In the preceding lectures I described the moral and physical conditions of our species, which are most appropriate for the increase and multiplication of mankind; the proper age for the propagation of healthful offspring; the good and bad effects of generative function on parents and their infants; the disqualifications, both moral and physical, for marriage; the moral, hygienic, and medical treatment of pregnant, parturient, puerperal, and lactiferous women, as regards their own well-being and that of their infants. In the former part of this course of lectures on gynecology, anthropogeny, and paedonology, or, as it is usually designated, midwifery and diseases of women and children, I communicated the received opinions on the reproduction of living beings, the generation or formation of the germs, embracing the latest conclusions respecting oology, or the history of the germ in the ovary before fecundation, or impregnation; and of embryology, or of the new being after its descent into the womb, its figure, structure, tunics, connexion with the mother, its nourishment by the maternal blood through the placenta, or after-birth; the peculiar mechanism of its circulation; the influence of the moral and physical states of the parent on the new being, from the moment of conception, during the periods of utero-gestation, or pregnancy, parturition, the puerperal state, and lactation. I have now to describe the medical management and cares necessary for the human offspring from the moment it has passed the portal of life; and then consider infantile hygiene and medicine, or the physical education and medical treatment of infants.

The infant in the womb, at the period of parturition, has all its organs developed, though many of these are inactive, its senses of vision, hearing, &c., and hence it was said by some to enjoy an existence analogous to vegetables, but birth elevates it to the existence of animals. This comparison is scarcely correct, inasmuch as the infant possesses the power of locomotion in the womb, and this is more perceptible during the interesting and astonishing process of parturition. The human offspring comes into the world the most feeble and helpless of animals, and requires numerous

cares for its preservation and well-being. It would be highly imprudent and dangerous to abandon it to itself in a state of helplessness and nudity. The first care it requires, after it comes into the world, is to raise its head and body, turn its back towards the genital organs of the parent, so that the water, or blood, which escapes from the womb immediately after the birth of the infant, may not pass into its mouth or nostrils, and prevent the ingress of air into the lungs. This plan should be adopted when the woman is delivered on either side, but if on the back, as in other countries, and sometimes in this, the infant should be placed transversely between the limbs of the parent. By attending to this precaution the new born infant will escape exposure to an air vitiated by the transpiration of the mother, and by the urinary and alvine evacuations, which are often spontaneously expelled during the last efforts of parturition. The next point to be attended to is to remove the infant from under the bed clothes, to ascertain, quickly, whether it be affected with asphyxia (still-born) or with apoplexy, the face being livid. As soon as the infant is born we observe the motion of its limbs, the dilatation of its chest, caused by the sudden ingress of the air, and this followed by contraction, which in general establishes respiration, or breathing, almost instantaneously. The establishment of complete respiration renders the infant totally independent of the parent, and justifies the separation of the communication (navel string or cord) between them.

Section and Ligature of the Umbilical Cord, or Navel String.—The father of medicine advised the division or cutting of the funis umbilicalis, or navel cord, so soon as the infant had respired and cried; and this advice may be followed in a preponderating majority of instances, though circumstances may occur to prevent us from adopting it. When the parturition has been tedious, and the head of the infant subjected to considerable and long continued pressure, or when the navel cord is twisted round the neck, compresses the jugular veins, and causes cerebral congestion, it may not respire for ten or twenty minutes after birth, it is said to be still-born, or rather asphyxied, or apoplectic, and, in such cases, the cord must be divided, though respiration has not commenced, to disgorge the brain and to favour the establishment of breathing. But as a general rule, the navel cord ought to be divided as soon as respiration is established, because after this process commences, the pulsations of the umbilical arteries in the cord cease, this last collapses more or less, and no more blood passes through the umbilical arteries, or from the infant. (Denman, Leroy, Girard.) These authors concluded that the application of the ligature immediately after the birth of the infant, and before the umbilical arteries had ceased to pulsate, caused congestion in the liver, abdomen, lungs, and brain,

as the blood regurgitated in the arteries and aorta; and that jaundice, colic, difficulty of respiration, and lividity of the face were the consequences. I think this pathology is objectionable and inaccurate, or at least that it requires to be proved. The section of the umbilical cord, or navel string (omphalotomy), was considered by the ancients an operation of considerable importance, as two arteries and one vein were incised or divided. The Arabian physicians proposed, before the section of the cord, to remove, by repeated lotions, the fluids which fill the cellular tissue, which connects the umbilical vessels. It was hoped, by this precaution, to preserve the infants from icteritia (yellow gum), crusta lactea (milk-rash), small-pox, convulsions, &c. It is unnecessary to comment upon this error. The expression of the blood and mucosities from the umbilical cord, before applying the ligature for the above reason, and also for the prevention of convulsions, was advised by the Arabians, by Abbé Byzance, and Claude Sarton. Others recommended the blood to be pressed towards the umbilicus, or navel, from the fear of removing from the infant a principle of strength and vigour, a proceeding which Aristotle taught the Grecian mothers. It was also sagely held, that the length of the virile member, and the profundity of the uterus depended upon the length of the remainder or root of the umbilical cord left after its section. This is a popular error even in our day. I fully agree with Professor Capuron, that "these are questions which cannot be described without compromising the honour of modern physiology. They appear so frivolous at first sight, that the vulgar and even the most ignorant reject them with disdain." The ligature should be tied about two inches from the umbilicus, or navel. It was considered for ages past, that the ligature and section of the cord were indispensable, but about the commencement of the seventeenth century, John Fantoni, Professor of Anatomy at Turin, doubted the absolute necessity of this operation. Alberti held the same opinion. (*De funiculi umbilicalis neglecta alligazione in causis infantisidii limitanda.*) Schulzius, in 1733, sustained the same doctrine in his dissertation (*an umbilici deligatio in nuper natis absolutè necessaria sit*). M. Leroy defended the same conclusion in 1771 (*Médecine Maternelle*, 1830). These, with Daniel and other distinguished professors, concluded, that if the infant respired perfectly after birth, the divided vessels of the umbilical cord need not be tied, but that a ligature was necessary when the respiration was feeble or imperfect. M. Leroy pressed his hands on the chest of a new born infant, and while he impeded the motion of the ribs, the umbilical arteries, which were divided, bled freely, but as soon as he removed the pressure, and that the breathing was re-established, the hæmorrhage ceased. We observe, in general, that the umbilical arteries cease to pulsate in a few minutes after delivery,

and that the cord may be divided or cut without the least hæmorrhage. This remarkable phenomenon is attributed, by M. Velpeau, to the change of the direction of the iliac arteries, to the difficulty which the blood encounters in passing into the aorta through the arterial canal (ductus arteriosus), and into the cord, or navel string, through the umbilical arteries, which constantly occurs in the normal circulation, and in reality depends upon the attractive force of the placenta upon the blood, replaced by that of the respiratory organs, in such manner that the placenta, or after birth, is only an inert body, deprived of vitality, which the blood abandons, as it does in a limb affected with gangrene, or asphyxied. Vesalius and Beclard have seen the arteries of the cord pulsating in the fœtus in the incised womb of living animals at the end of gestation, but the pulsations ceased as soon as the membrane, surrounding the fœtus, was broken, and the air rushed into the lungs. Velpeau has observed the same fact on the human fœtus, expelled at the sixth month, and surrounded by the membrane. Notwithstanding these authorities, there is not the slightest doubt but that the arteries may bleed freely after respiration is complete; and examples are not wanted to prove, that the infants have been destroyed by umbilical hæmorrhage, or bleeding from the navel. Every one engaged in obstetric practice must have seen bleeding from the navel string after the section of it; and hence the universal practice of applying a ligature for its prevention. It is true, the animals dispense with a ligature, but with them the cord is lacerated or divided with the teeth, and hæmorrhage is thus prevented. Travellers assert, that the natives of the Brazils and the Hottentots chew and lacerate the cord with their teeth, and never apply a ligature.

The ligature consists of a piece of strong thread, twice or thrice doubled and twisted, and sometimes waxed, which is placed round the umbilical cord or navel string, within two inches of the abdomen of the infant, and tied with a single knot; it is again brought round the cord, and tied with a double knot. It must be firmly tied to prevent hæmorrhage or loss of blood, but never so tightly as to cut the cord or the vessels in it. A second ligature with a single knot is placed two or three inches near the mother; the cord is then divided with a pair of scissors, and the infant placed on a piece of warm flannel and handed to the nurse. The ancients did not use iron instruments for cutting the umbilical cord, because they considered them dangerous between the tropics. They maintained, that the edges of such instruments were covered with a rust or oxide, which could be seen with a microscope, and which was more abundant in the tropics than in the more temperate climates. These particles were detached in the operation of cutting the umbilical cord, and applied to the orifices of the three vessels, and

were said to produce deleterious effects in warm climates, which were known to the ancients, and of which the moderns have no knowledge.

M. Leroy asserts, that it was to avoid these dangers Moses ordered circumcision to be performed with a knife of stone. The Jews, in all climates, without knowing the reason of the precept of their legislator, at least those who observe, with exactitude, their law, do not use for this purpose any cutting instrument of steel or iron. M. Leroy ascribes the immense mortality among the negro children, caused by convulsions and tetanus, to the use of such cutting instruments; and to obviate such consequences, he advises the edge to be greased, so as to remove the oxide. "It is therefore necessary," says he, "to grease slightly the scissors for cutting the cord; and by this means, in our climate, cutting instruments of steel are not dangerous: between the tropics they would be less so; but it would be better, in these regions, to make this section without steel or iron. I advise young students to use the same precautions for all cutting instruments, and in all operations. Many have informed me that they have observed this practice evidently useful, and that the wounds inflicted have been less dangerous. After blood-letting we sometimes observe supuration in the wound, though made with a new lancet. These accidents rarely occur to those who have observed the precaution above indicated." M. Capuron comments on the preceding remarks in these words:—"Vain alarms and ridiculous precautions, the inutility of which falls before our eyes, and which do not deserve to be seriously refuted." It is very true, that in these climates bad effects rarely follow the section of the cord, though the scissors be not greased; but this does not prove the innocuousness of the practice in tropical regions.

With respect to the phlebitis consequent to venesection and other surgical operations, there is nothing more certain. I remember two cases of this kind; one was a male patient in the Royal Infirmary of Edinburgh, who was bled with a new lancet; the other was a female in Fetter-lane, whose arm swelled to a great size, erysipelatous inflammation traversed both sides of the body, accompanied by typhus, and after several weeks' suffering recovery happened. Though I admit, with Professor Capuron, that such cases are rare, I cannot help thinking, that were the edges of surgical instruments covered with platina, in the same manner as Dr. Wollaston had razors manufactured, it would be a decided improvement. The superiority of such instruments over those now made would be, that they would retain the finest edge for a long time, and be almost free, if not entirely so, from oxidation or rusting.

After the first ligature is placed on the umbilical cord, within two inches of the infantile abdomen, or at a much greater distance ac-

cording to others, the cord is squeezed between the index finger and thumb towards the mother to the extent of an inch or two, and a second ligature with a single knot is applied. MM. Capuron, Gardien, Velpéau, and other French writers, consider the second ligature not only unnecessary but injurious, except in cases of twins, by causing congestion of the placenta, increasing its volume, and thereby retarding its expulsion. They allege, that the maternal blood cannot escape through the divided umbilical vein to any serious extent, that the placenta discharges itself, becomes reduced in volume, and is more easily expelled. "A severe hæmorrhage, even by the cord," observes M. Gardien, "does not render this ligature necessary. The loss soon reappears after it has been suspended for some minutes. The blood which escapes from the uterine vessels on account of the inertness of the womb cannot escape by the cord, engorges the placenta, and destroys its adherences with the womb. Hæmorrhage of this kind, as well as others, prevents the indication of exciting the contractions of the womb for removing the inertness which is the cause."—(*Dict. des Sciences Méd.* art. CORDON.) M. Leroy, on the contrary, recommends the second ligature, "because the blood which escapes from the vessels of the mother (uterine), in greater or less quantity, will enfeeble the womb, cause inertness and fatal hæmorrhage."—(*Médecine Maternelle*, 1830.) The most eminent obstetricians of this country apply a second ligature (Hamilton, Burns, Denman, Blundell, Conquest, &c.). In my opinion it is necessary, and does not retard the expulsion of the placenta. It is admitted by all obstetric writers, that the centre of the placenta is first detached from the uterus by the contractions of this last organ, that a quantity of blood is effused between the placenta and womb, and that finally the circumference of the placenta is separated. It therefore follows, that the second ligature on the cord will cause, more or less, engorgement of the placenta, detach it by rupturing its adherences with the womb, and facilitate its separation and expulsion. The second ligature prevents the loss of maternal blood by the cord; and it is by no means proved, that the blood which causes the placental engorgement, or the quantity of blood effused between the uterus and placenta, is more injurious to the woman than if the cord was allowed to bleed freely. Some recommend the umbilical cord to be tied before cutting it, which is the usual practice in these countries; others, to make the section, remove the infant, and then apply the ligature. Care must be taken that there is no part of the intestine in the cord (omphalocele) before the ligature is applied. When the umbilical cord is tied and incised, the next cares required by the infant are washing and dressing.

Washing and cleaning the Infant.—The skin of the infant at birth is covered with an unctuous, whitish substance, and sometimes

mixed with blood, which is, according to some, a secretion from the skin, while others consider it an albuminous deposit from the liquor amnii or fluid which surrounds the infant in the womb, upon the body of the foetus. It is most abundant in the groins, between the thighs, axillæ (armpits), neck, behind the ears, and in all situations in which surfaces approach each other. This substance obstructs the pores of the skin, suppresses insensible perspiration or transpiration, and ought to be removed by ablation or washing. It is absurd to suppose, as some authors have done, that the removal of this matter is contrary to the object of nature; that the washing of the infant exposes it to the impression of the air, produces cough, griping, convulsions, &c. The refutation of this error is afforded by the proceeding of the inferior tribes of mammiferous animals, as the cow, the goat, &c., for its removal. Besides, many infants are born without it. The vulgar prejudice of leaving it on the head to strengthen the fontanelle or opening, which prevails in France, is still more ridiculous. In this country, even amongst the vulgar, it is removed by washing. After the ligation and section of the umbilical cord, the infant should be enveloped in a piece of warm flannel, its mouth and nose being uncovered, and then removed into another apartment.

The ablation or washing of the infant should be performed in an adjoining chamber to that in which the mother has been delivered, as nurses in general make much noise and bustle during this process. They also handle the delicate infant very roughly, and cause it to scream during the whole time occupied in ablation, and therefore disturb and distress the mother, who ought to be kept quiet and tranquil, more especially when delicate, or after a tedious labour. In such cases she should not talk, or be spoken to, without absolute necessity.

The manner of washing a new-born infant is simple. A lather of mild soap is gently applied to the head with a piece of soft flannel or sponge, care being taken not to allow the eyes to be irritated by this fluid. Spirit of any kind is unnecessary, though frequently employed by nurses, unless when the scalp is tuffed. The eyes should be washed with tepid water only, and should not be exposed to the light of a candle or fire, as is usually the case. The head and ears are now dried by means of a soft old napkin, and a flannel cap is put on. The neck, body, limbs, with all their creases, should be thoroughly washed; and, when the sebaceous or unctuous matter is very adherent, the addition of some olive oil, lard, fresh butter, or any fresh grease to the soap lather, or to the affected part will facilitate its removal. In performing this task, it is desirable that it should be done as quietly as possible, all hasty and violent movements or turnings of the infant should be carefully avoided.

Sometimes the infant is immersed in a warm bath, imitating the position which it had in the amniotic fluid, or that which surrounded it before birth. When the infant is delicate or feeble, the addition of a small quantity (a teaspoonful) of wine, brandy, or other ardent spirit forms an excellent tonic bath, which strengthens and reanimates the new being when in a languishing or dying condition. Care must be taken not to add too much spirit, or the delicate, soft, and tender skin will be excoriated or inflamed, or convulsions, apoplexy, or death induced. The body is now to be wiped dry with a fine soft napkin, the groins, internal surfaces of the thighs, neck, behind the ears and armpits powdered with fine hair powder, or finely powdered starch, and the infant is then dressed.

In former times, the body was powdered with fine salt, afterwards washed with warm wine, and then dressed with warm clothing, a practice still advised by M. Leroy, but I believe, never followed. The custom of the ancient Germans, Britons, Greenlanders, Scotch and Irish, according to Locke, Italians and Scythians, who imitated the Lacedæmonians, in plunging their new-born infants into cold water, and sometimes mixed with ice for purpose of rendering the body less sensible and more robust, is hurtful and condemnable. The inhabitants of Latium, in Italy, adopted this custom, of which Virgil has said, *Æneid*, Lib. ix. v. 604,—

“*Durum a stirpe genus, natos ad flumina primum
Deferimus, sævoque gelu duramus et undis.*”

This custom, which is still observed in some parts of Russia and Lapland, so far from strengthening the constitution in all cases, is destructive to one half of the infants by inducing convulsions. The frail and delicate body of a new-born infant, which has left a temperature of 98°, cannot be plunged into cold or iced water without certain injury, if not certain destruction. It must also be remembered, that the vigour and robust constitutions of the northern people depend upon their regimen and active exercise, and the mortality of their infants is immense. If the people of northern nations are vigorous, it is because their feeble and delicate infants are destroyed by exposure to the custom under consideration, and by the inclemency of the seasons. The practice which they pursued, and which no longer exists, except in the places alluded to, was adopted on the grounds of having strong athletic citizens in the state, as infirm individuals were considered more embarrassing than useful; but in all civilised nations at present, infants, whether delicate or vigorous, are entitled to equal protection from parents and society at large.

Medicated, alcoholic, and strengthening baths, which were formerly and even now in use, are to be prescribed by medical practitioners only, when the infant is feeble or

languishing; while simple tepid baths or ablutions can only be employed with equivocal advantage by those unacquainted with the science of medicine. In conclusion, I must observe, that some ignorant midwives and nurses will attempt to wash the new-born infant with cold water, or immerse it, even in winter, in a cold bath, unless prevented by the medical practitioner. When the infant is washed and dried, it is enveloped in a warm flannel, its body is to be examined to ascertain its proportions or deformities, and dressed as speedily as possible.

Swathe and Dress of the Infant.—In ancient times the new-born infant was swathed from head to foot, like an Egyptian mummy, a proceeding termed swaddling, and this injurious custom still remains in use in many of the French provinces. Bandages are placed round the head and neck to keep the former steady. All modern Gallic obstetric writers condemn these proceedings. The proper mode of dressing a new-born infant deserves particular attention. The first part of the dress of an infant is applied to the remains of the umbilical cord in the following manner:—The nurse takes a soft piece of old linen, about two inches square, cuts a small circular hole in its centre, through which she brings the remaining part of the navel cord, and then envelops it. She next turns it towards the chest of the infant, and places a small flannel bandage or roller over it, and round the body. This should be secured by tapes. The object in dressing the navel cord is to prevent it irritating the skin of the infant. Some writers recommend a small pad over the dressing, but this is seldom applied in this country. The bandage should not be too tight or too loose, as in the first instance it is intended to secure the navel cord, and secondly to prevent the starting of the navel, hernia, or omphalocele. The dress of a new-born infant is plain and simple. As a general rule, all compression of the chest or abdomen is highly injurious: it renders the respiration difficult, prevents the return of blood from the head, causes congestion, apoplexy or hydrocephalus, derangement of the digestive organs, hiccup, vomiting, griping; the development of the body is arrested, the action of the muscles, including the motion of the limbs, is impeded, the body becomes curved according to the direction of the pressure, the spine and limbs become deformed, or, to use a popular phrase, "grow out," or are rickety, while the vigour and beauty of the structure are diminished or destroyed.

The Asiatics, Turks, Africans, and all people who allow the free development of the body, chest, shoulders, back, and limbs are remarkably large and vigorous. In fact, the custom of swathing or swaddling is totally abandoned in all civilised countries, unless among a small portion of the lower orders. The bad effects of the custom shall be further described hereafter.

Another cruel practice is adopted by nurses, and that is, "squeezing the breasts of infants to get out the milk." This proceeding is useless, and often induces inflammation and supuration of the injured part. It is true that gentle compression causes a slight discharge of a thin fluid, and if resorted to at all, it must be with proper caution. Most infants do well without such an operation.

Almost every part of the infant's dress should open on the back, and be fastened by tapes or buttons, and pins ought to be entirely laid aside. The absurd practice of tightening the cap-tapes under the chin to make "the baby look well," is highly to be condemned. The infant should be at ease, and enjoy perfect freedom of motion of its superior and inferior extremities. It therefore follows, that the triangular doublet or napkin placed round the lower part of the abdomen, fastened in front, and then the remaining angle of it brought between the lower limbs, and pinned to the former part, should not be too tightly applied, as it would prevent the free motion of the lower limbs.

When the infant is dressed it is enveloped in flannel, the face being uncovered, and placed on its right side in its cot, which is preferable to the bed of the mother, as this is too warm, and predisposes it to catarrh, or cold, or snuffles which will prevent it from sucking. But maternal affection leads to the violation of this precept. Every mother longs to gaze upon her infant, and must be gratified. The beautiful language in which the illustrious Byron apostrophised his daughter on the morning of her birth admirably illustrates parental affection.

"Hail to this teeming stage of strife!

Hail, lovely miniature of life!

Pilgrim of many tales untold!

Lamb of the world's extended fold!

Fountain of hopes, and doubts, and fears,

Sweet promise of ecstatic years!
